2. Welcome to Massive X

Massive X is the successor of Massive, the iconic synth that helped build musical genres. Expanding on this legacy, Massive X provides you with all the features you need to create any sound imaginable. By combining innovative sound generators and processors with modular routing and expressive modulation, Massive X not only facilitates common synthesis techniques but also invites you to experiment and bring new ideas to life.

We hope you enjoy using this fantastic instrument!

What's new

New features in Massive X 1.6

The following new features have been added to Massive X:

- **Player version:** Now Massive X is also available as Massive X Player with a reduced feature set.
- **Play view:** The new Play view includes a set of intuitive and creative tools: You can quickly load a preset with the **side pane browser**, play with its most important parameters with the **Macros 1–8**, and create evolving sounds by morphing between four variations of the preset, either manually in the **Morpher** or automatically using the **Animator**. Refer to [Play view](#).
- **View switching buttons:** Massive X now provides a streamlined interface with two or three views and their respective buttons: the new Play view, the Browse view, and the Edit view (not available in Massive X Player).
- **MX Player Library:** The new MX Player Library provides 60 presets.
- **Loading presets from the Browser:** Single-clicking a preset loads it and keeps the Browse view open, while double-clicking the preset loads it and closes the Browse view.
- **Animator on/off switch:** The Animator of the new Play view can be turned on and off using a new button added to the Macro bar in the Browse view and in the Edit view (not available in Massive X Player).
- **Choosing the default view:** In the full version of Massive X, a new option in the Settings menu lets Massive X open the Edit view at launch instead of the Play view. Refer to [Settings menu](#).
- **Load Init Preset:** The empty Init preset is not loaded by default anymore. Instead, you can load it using a new **Load Init Preset** entry from the Settings menu. Refer to [Settings menu](#).
- **Massive X Factory Library:**
 - The Genre types have been inserted as comments into the presets to allow text search.
 - The factory libraries for the Massive X versions 1.0 to 1.5 were consolidated into the **MX Factory Library**, and the versions were added as comments to allow text search.
 - The “Patch and Play” bank was consolidated into the **MX Factory Library**.

Please update the Massive X Factory Library using Native Access.

New features in Massive X 1.5

The following new features have been added to Massive X:

- **Multi Compressor:** The Multi Compressor is added to the Stereo Effects, providing multiband upward and downward compression. Refer to [Multi Compressor](#).
- **New Presets:** 60 new presets have been added to the Factory Library. Please update the Massive X Factory Library using Native Access.

New features in Massive X 1.4

The following new features have been added to Massive X:

- **Browser :** The new Browser provides expanded functionality for filtering sounds by tags, text search, User presets and Favorites. Refer to [Browser and presets](#).
- **Bass Enhancer:** The Bass Enhancer is added to the Insert Effects, providing specialized bass enhancement that brings presence and drive to low frequency content. Refer to [Bass Enhancer](#).
- **LP4 Filter Mode:** LP4 (4-pole low-pass) mode has been added to the SVF filter, attenuating frequency content above the cutoff frequency with a slope of 24 dB/Oct. Refer to [SVF](#).

- **Control Sensitivity:** Control Sensitivity is added to the Settings menu, with nine options ranging from 25% to 250%. Refer to [Settings menu](#).

New features in Massive X 1.3

The following new features have been updated or added to Massive X:

- **Parameter Values Displayed:** Parameter values have been added to the slider, knob, and Macro controls. Values appear when hovering over the parameter. See [Control elements](#).
- **Key Track Mode:** Key Track mode has been added to the Noise section. It can be accessed through a dropdown menu by the Pitch parameters in the Noise player. See [Noise overview](#).
- **Noise One Shot:** One Shot mode has been added to the Noise Engine. See [Noise Engine](#).
- **New Noisetables:** 50 new Noisetables and 20 new presets have been added.
- **New Noisetable Category:** Transient category has been added to the Noisetable menu, specializing in percussive sounds and fast-attack samples that work especially well with One Shot mode.
- **Custom User Noisetables:** Custom user samples can now be loaded into the Noise player. See [User noisetables](#).
- **New Presets:** 20 new presets have been added to the Factory Library. They are accessed from the **New in 1.3** category in the Browser. See [Browser and presets](#).

New features in Massive X 1.2

The following new features have been updated or added to Massive X:

- **Importing Presets by Drag-and-Drop:** Presets can be added to the User Presets folder by dropping files on the Massive X user interface. Refer to [Importing a preset](#).
- **Remote Octave:** The Lightguide on Komplete Kontrol S-Series keyboards indicate the Remote Octave of the Performer. Refer to [Remote Octave](#).
- **Anonymous Data Tracking:** Feature based data tracking has been added to facilitate further improvement of the user experience. For more information on Usage Data Tracking, refer to [Settings menu](#).
- **Demo Time Increase:** Demo time has been increased from 30 to 60 minutes.
- **New Presets:** 100 new presets have been added to the Factory Library. Refer to [Browser and presets](#).

New features in Massive X 1.1

The following new features have been added to Massive X:

- **ADDED:** Exciter, Amp and Modulation Envelope displays reflect their actual state and respond to user input. Refer to [Modulators](#).
- **Dark, Light and Flat Modes:** Dark, Light, Flat Default, Flat Dark, and Flat Light themes have been added. The Flat themes increase compatibility with older graphic cards. Refer to [Settings menu](#).
- **Rise/Fall Parameter Display:** The Rise/Fall parameter in both the LFO Switcher and LFO Random Envelope now visually displays the actual parameter state and responds to user input.
- **Category for New Factory Presets:** A separate category type has been added in the Browser for new Factory presets, based on release iteration. This provides quick access to any new presets.

- **Tracker Grid Labels:** Grid labels have been added to the Tracker.
- **New Presets:** 60 new presets have been added to the Factory Library. Refer to [Browser and presets](#).

Document conventions

In this document the following formatting is used to highlight useful information:

<i>Italics</i>	Indicates paths to locations on your hard disk or other storage devices.
Bold	Highlights important names, concepts, and software interface elements.
[Brackets]	References keys on the computer keyboard.
►	Denotes a single step instruction.
→	Denotes the expected result when following instructions.

The following three icons denote special types of information:

The **light bulb** icon indicates a useful tip, suggestion, or interesting fact.

The **information** icon highlights essential information in a given context.

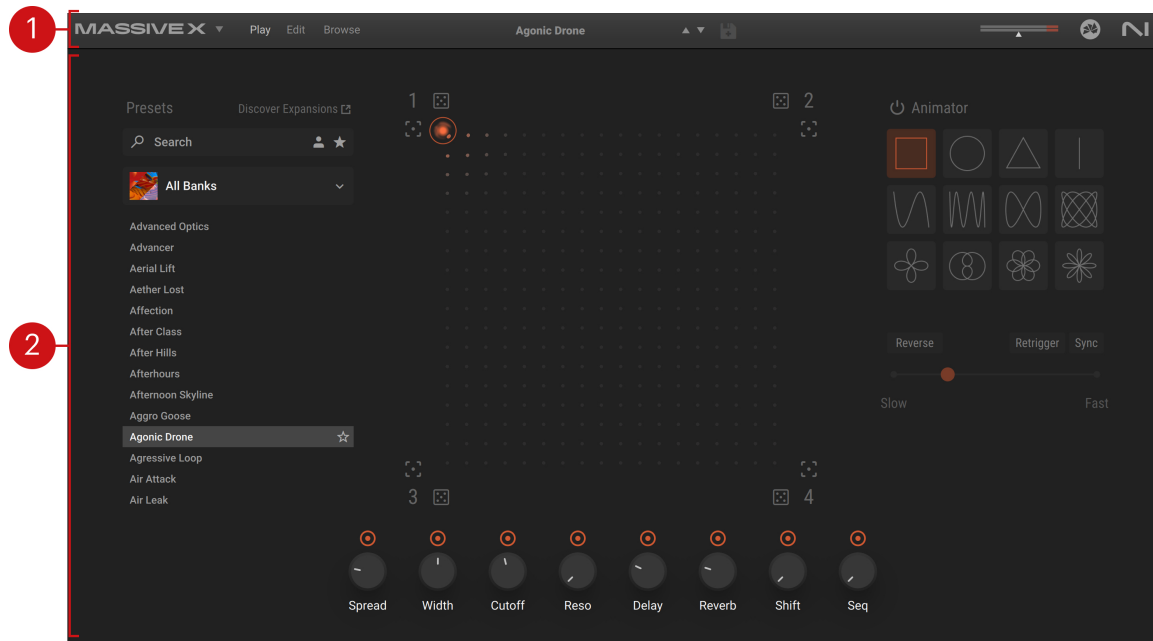

The **warning** icon alerts you of potential risks and serious issues.

3. Massive X overview

This chapter introduces the main controls and areas of Massive X.

When you first open Massive X, you see the default Play view, along with a set of global controls at the top of the window:

1. **Header:** Always visible at the top of the window, the Header provides important elements controlling, for example, the displayed view, the loaded preset, the main volume level, and various instrument settings. Refer to [Header](#).
2. **Instrument views:** Below the Header, the biggest part of the instrument window can display different views:
 - The **Play view** (depicted above) provides intuitive tools to quickly generate evolving sounds from your libraries and Expansions. Refer to [Play view](#).
 - The **Edit view** (not available in Massive X Player) lets you configure Massive X's sound engine in detail. Refer to [Edit view](#).
 - The **Browse view** contains the Browser, which lets you quickly find and load the desired presets from your libraries and Expansions. Refer to [Browser and presets](#).

Header

Sitting at the top of Massive X's window, the Header provides easy access to a number of important elements, including the different views, the Browser, the Main Volume, and the Settings menu.

1. **Massive X logo:** Opens the About dialog with information about the version number, license, and credits of the instrument.

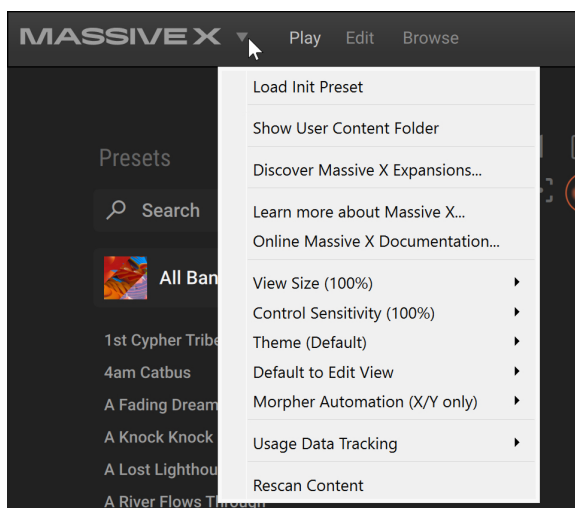

2. **Settings menu** (downward arrow): Provides options for managing user presets, adjusting the instrument's visual appearance, and a few other settings. Refer to [Settings menu](#).
3. **View buttons**: These buttons let you switch between the instrument views:
 - **Play**: Opens the Play view. Refer to [Play view](#).
 - **Edit** (not available in Massive X Player): Opens the Edit view. Refer to [Edit view](#).
 - **Browse**: Opens the Browse view and the Browser. Refer to [Browser and presets](#).
4. **Preset selector**: Shows the name of the loaded preset. You can click the top and down arrows to load the previous or next preset from the current Results list: In Play view this will be the Results list in the [side pane browser](#), whereas in Browse view or Edit view this will be the Results list in the [Browser](#). A little star appears next to the preset name to indicate that your modifications have not been saved yet.
5. **Save Preset button** (floppy disk icon): Saves the current state as a user preset. Refer to [Saving a preset](#).
6. **Main Volume**: Adjusts the output level of Massive X. The meter shows the current level of the output signal.
7. **NI logo**: Opens the About dialog with information about the version number, license, and credits of the instrument.

Settings menu

The Settings menu in the Header provides options for managing user content, adjusting the visual appearance of the interface, setting the control sensitivity, and adjusting the Morpher automation. You can also access learning resources, discover Massive X Expansions, and set usage data tracking.

- To open the Settings menu, click the downward arrow icon next to the Massive X logo in the Header.

The Settings menu contains the following entries:

- **Load Init Preset**: Loads a standard template preset with basic settings, allowing you to start designing a new sound from scratch.
- **Show User Content Folder**: Opens the folder on the hard drive containing your user content. Refer to [Managing user presets](#).
- **Discover Massive X Expansions...**: Opens the Massive X Expansions page on the Native Instruments website.

- **Learn more about Massive X...:** Opens the Massive X product page on the Native Instruments website.
- **Online Massive X Documentation...:** Opens the online Massive X manual (the document that you are reading).
- **View Size:** Provides eight size settings for the plug-in and saves the selected size as the default.
- **Control Sensitivity:** Provides nine settings for the sensitivity response of knobs and sliders.
- **Theme:** Provides four different visual appearances for the plug-in. In addition to the default setting, a **Dark** color scheme is available, as well as **Flat** versions that are optimized for efficiency.
- **Default to Edit View** (not available in Massive X Player): When this option is active, Massive X first opens in Edit view instead of Play view.
- **Morpher Automation:** Lets you choose which parameter changes are exposed to your DAW when you move the [Morpher cursor](#). Refer to [Controlling the Morpher using MIDI or host automation](#).
- **Usage Data Tracking:** Offers more information about usage data tracking, and the option to activate or deactivate the feature.
- **Rescan Content:** Updates the Browser to reflect all changes made to the User Content folder. Refer to [Managing user presets](#).

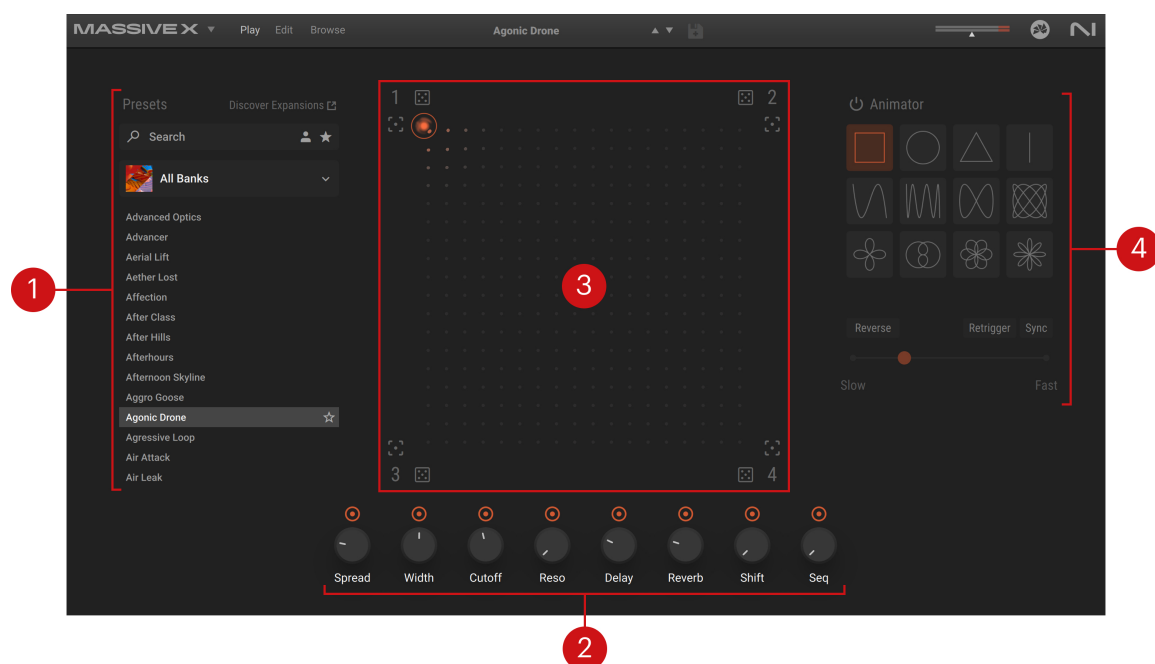

4. Play view

Massive X's **Play view** lets you quickly load a preset, play with its most important parameters, and create evolving sounds by morphing between four variations of the preset, either manually or automatically following a predefined curve.

► Click **Play** in the Header to open the Play view.

The Play view contains the following areas:

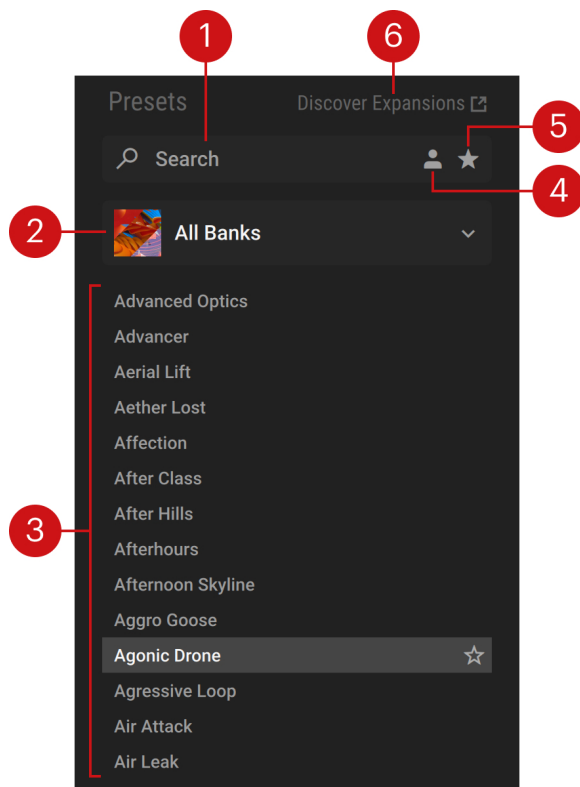

1. **Side pane browser:** Lets you quickly search and load presets from your libraries and Expansions. Refer to [Side pane browser](#).
2. **Macros 1–8:** Provides access to the first eight Macros. Refer to [Macros 1–8 in the Play view](#).
3. **Morpher:** Adjusts the morphing between four different snapshots of the preset, each snapshot containing another set of values for the Macros 1–8. Refer to [Morpher](#).
4. **Animator:** Configures an automatic morphing between the snapshots. Refer to [Animator](#).

Side pane browser

The side pane browser provides a reduced version of the full Browser available in the [Browse view](#). You can use it to quickly browse and load presets without leaving the Play page.

The side pane browser contains the following elements:

1. **Search field:** Filters the presets in the Results list according to the text entered in the field. The search engine considers the preset name, author, Character and Sound Type tags, and product name.
2. **Product selector:** Displays the selected factory library or Expansion. Clicking the product name opens a menu where you can select another product from the factory libraries and Expansions installed on your computer. Selecting a product filters the Results list with the relevant presets. You can also select **All Banks** at the top of the menu to show the presets from all your products. The selected entry is synchronized between the side pane browser and the [Browser](#).
3. **Results list:** Displays the presets corresponding to your search criteria. The presets are listed in alphabetical order and the selected preset is highlighted. You can click a preset to load it. As you hover over any preset with your mouse, a star icon appears on the right: If you click the star, the preset is set as Favorite and its star lights up. Clicking a lit star will remove the preset from your Favorites.
4. **User Content button:** Filters by user content. When activated, the Results list only shows user presets. When deactivated, the Results list only shows presets from your factory libraries and Expansions. For more information on user presets, refer to [Using presets](#). The state of this User Content button is synchronized between the side pane browser and the [Browser](#).
5. **Favorites button (star icon):** Filters the presets in the Results list by Favorite tags. You can assign the Favorite tag to any preset in the Results list, creating quick access to a custom collection of your most beloved presets sounds.
6. **Discover Expansions link:** Opens the Massive X Expansions page on the Native Instruments website.

Macros 1–8 in the Play view

The eight Macro knobs at the bottom of the Play view represent the first eight Macros of the loaded preset.

i Macros are shortcuts assigned to single or multiple parameters of Massive X. They are specific to each preset. In the full version of Massive X, you can customize the Macro assignments. Macros also give you access to host automation and MIDI control. For more information, refer to [Macros](#).

For each Macro, the following elements are available:

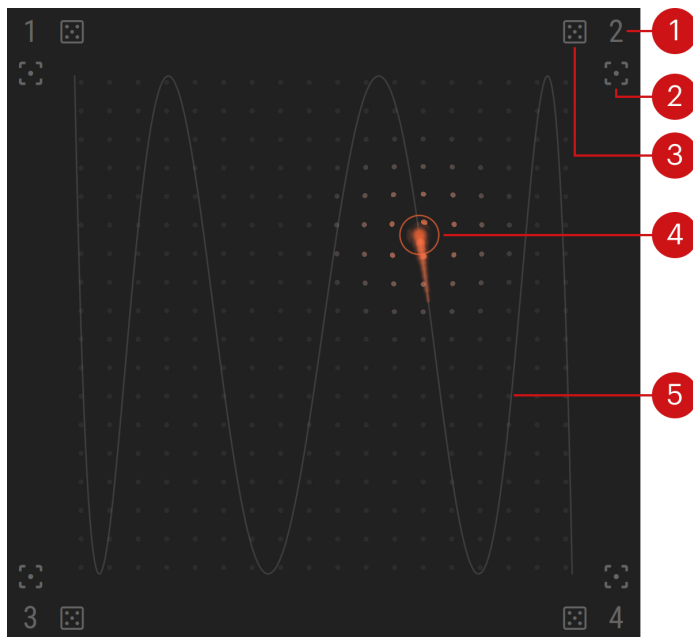

- 1. Macro label:** Describes the Macro's purpose or controlled parameter(s).
- 2. Macro knob:** Adjusts the Macro value, which in turn affects the value(s) of the controlled parameter(s). As you hover over the knob with your mouse, the current value appears below. You can click the knob and drag your mouse vertically to change the Macro value, or double-click the knob to reset it to its default position.
- 3. Morph switch:** When this is on (default state), the Macro knob is linked to the [Morpher](#) above: The knob value depends on the position of the Morpher cursor. If you deactivate the Morph switch, the Macro knob stays unaffected as the Morpher cursor moves. For example, if a Macro is controlling the global amount of reverb, you could deactivate its Morph switch to keep the same amount of reverb while morphing other parameters.

Morpher

The Morpher lets you define four distinct sets of values for the [Macros 1–8](#), called **Macro snapshots**, and morph some or all the Macro values between these four snapshots. The Morpher shows a square field in which each corner represents one snapshot. The position of the Morpher cursor in the field determines the Macro values according to how far the cursor is from each corner.

The Morpher contains the following elements:

1. **Recall Snapshot button (1–4):** When you click the snapshot number **1–4** the Morpher cursor jumps to that corner and the Macros with an active **Morph switch** take the values of this snapshot.
2. **Store Snapshot button** (focus icon): Stores the current values of the eight Macro knobs into this snapshot. The Morpher cursor additionally jumps to that corner. From now on, these Macro values will be recalled each time you click this snapshot number, and they will be used as reference when calculating the morphing values relatively to this corner.
3. **Randomize Snapshot button** (dice icon): Stores random values for the eight Macro knobs into this snapshot. The Morpher cursor additionally jumps to that corner. From now on, these Macro values will be recalled each time you click this snapshot number, and they will be used as reference when calculating the morphing values relatively to this corner.
4. **Morpher cursor:** Defines the morphing values of the Macros whose **Morph switch** is on. These values are computed from the respective distances between the Morpher cursor and each corner: The closer a corner, the closer the values will be to the snapshot in that corner. For example:
 - With the Morpher cursor in the top left corner, the Macro values are set to the values of snapshot **1**.
 - With the Morpher cursor halfway between the top right and bottom right corners, the Macro values are set halfway between the values of snapshot **2** and snapshot **4**.
 - With the Morpher cursor in the middle of the field, the Macro values are set to the average values of the four snapshots.

You can click and drag the Morpher cursor with your mouse to manually morph the sound, or you can click anywhere in the field to let the Morpher cursor jump to that position. You can also automate the movement of the Morpher cursor using the **Animator**. In addition, you can control the cursor using **MIDI or host automation**.

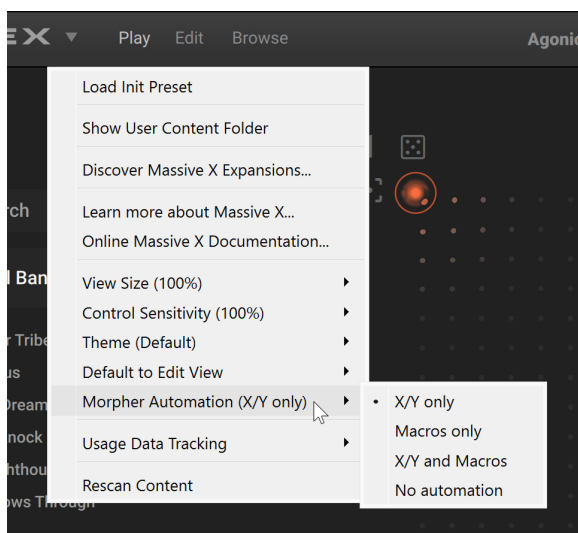

5. **Trail:** When the **Animator** is on, the selected trail appears in the field to indicate the path followed by the Morpher cursor. When the Animator is off, no trail is displayed.

i When you click the Store Snapshot or Randomize Snapshot button in a corner, the snapshot stores new values for all eight Macros, no matter whether their Morph switches are on or off. The Morph switches' on/off states only specify which Macros will follow the morphed values.

Controlling the Morpher using MIDI or host automation

You can control the position of the Morpher cursor from a MIDI keyboard/controller or using host automation in your DAW by assigning the cursor's horizontal (x axis) and vertical (y axis) positions.

Since the Morpher cursor modifies the values of the Macros 1–8, which are also available for host automation, you can choose which parameter changes will be exposed to your DAW when you move the Morpher cursor. This is done using the **Morpher Automation** entry from the [Settings menu](#) in the Massive X Header.

The following modes are available:

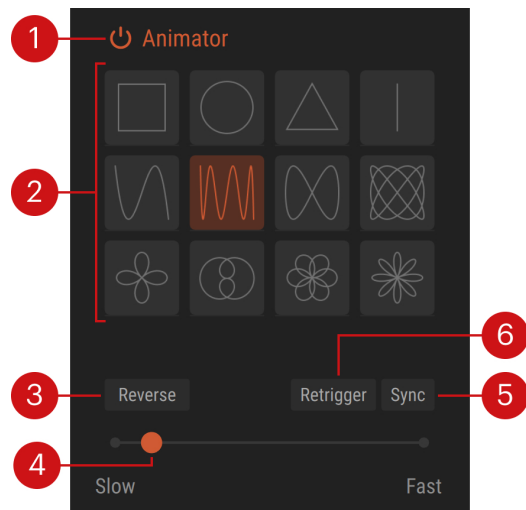

- **X/Y only** (default setting): When you move the Morpher cursor, only the changes in the cursor position (horizontal and vertical) will be reported to your DAW.
- **Macros only**: When you move the Morpher cursor, only the resulting changes in the Macro values will be reported to your DAW.
- **X/Y and Macros**: When you move the Morpher cursor, both cursor position and the resulting changes in the Macro values will be reported to your DAW.
- **No automation**: When you move the Morpher cursor, no parameter change will be reported to your DAW.

i These modes only affect the automation recorded when you move the Morpher cursor. Regardless of the mode selected here, your manual adjustments to the Macro knobs themselves will be reported to your DAW.

Animator

The Animator lets you automate the movement of the cursor in the [Morpher](#), and thereby automate the morphing of the Macro values.

The Animator contains the following elements:

1. **Animator on/off switch:** Activates or deactivates the Animator. When the switch is off, the whole Animator area is grayed out, and you can still adjust its settings but they will not affect the Morpher cursor until you reactivate the Animator. When the Animator is on, the Morpher cursor moves automatically and you cannot change its position by dragging it with the mouse.
2. **Trail selector:** Selects the trail followed by the Morpher cursor.
3. **Reverse:** Lets the Morpher cursor run in the opposite direction.
4. **Rate slider:** Adjusts how fast the Morpher cursor runs on the trail. When **Sync** is off, you can set the cursor speed anywhere between **Slow** and **Fast**. When **Sync** is on, you can adjust the cursor speed as the number of bars it takes to travel along the full trail: The available values range from **16** bars (slowest rate) to **1/8** bar (fastest rate).
5. **Sync:** When **Sync** is off, the Morpher cursor runs at its own pace. When **Sync** is on, the Morpher cursor is synchronized with the transport in your DAW as follows:
 - When **Retrigger** is off, the rate of the Morpher cursor is set relative to the tempo in your DAW, and its position on the trail is linked to the song position in your DAW. The cursor runs only when the playback is on in your DAW.
 - When **Retrigger** is on, the rate of the Morpher cursor is set relative to the tempo in your DAW. The cursor is always running, no matter if the playback is on or off in your DAW.
6. **Retrigger:** When **Retrigger** is on, the Morpher cursor restarts from the beginning of the trail for each new note. When **Retrigger** is off, the cursor position is not affected by the new notes.

5. Browser and presets

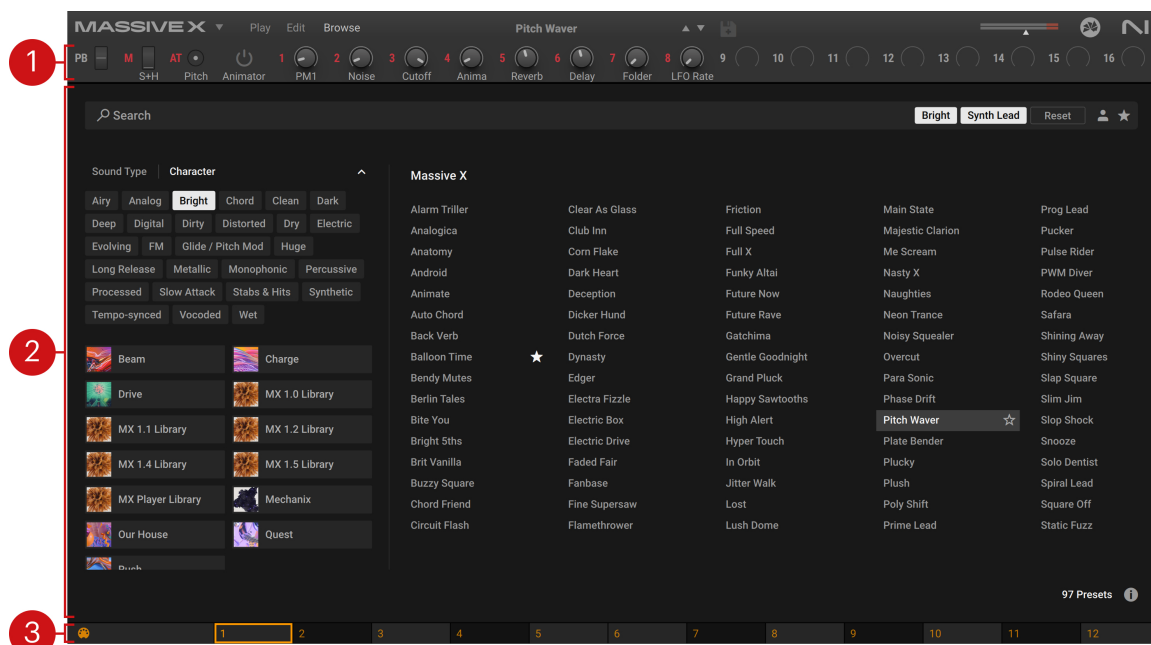

The Browser provides access to Massive X's libraries and Expansions. You can filter sounds by tags, text search, user presets and Favorites, helping you to quickly and intuitively find the right presets for your musical needs.

The Browser is the main part of Massive X's **Browse view**:

- Click **Browse** in the Header to open the Browse view and display the Browser.

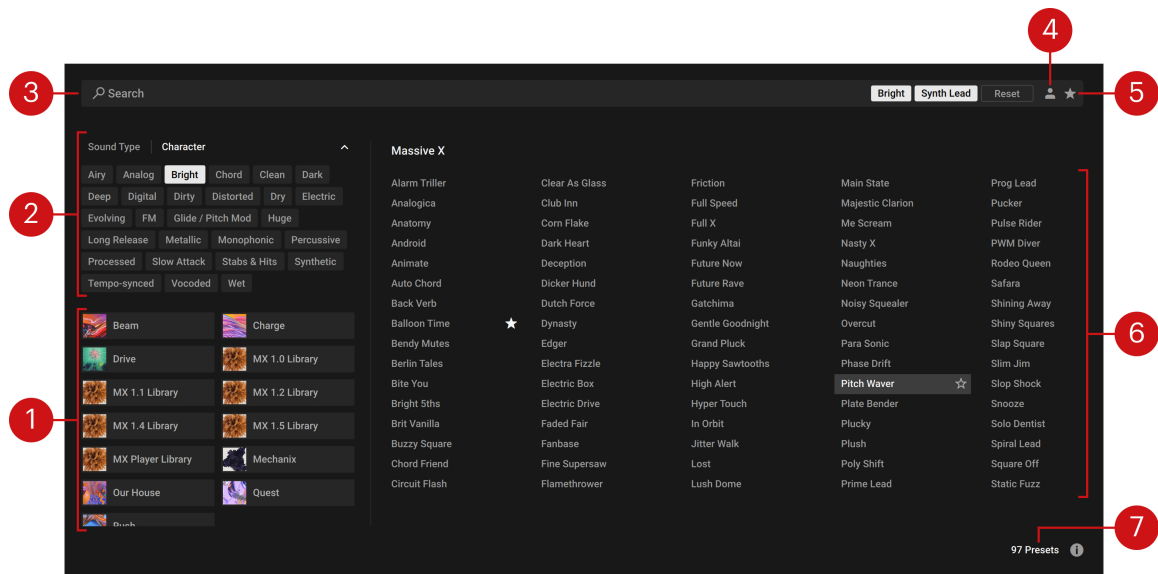

The Browse view includes the following areas:

1. **Macro bar**: Custom set of shortcuts assigned to single or multiple parameters of Massive X. The Macros also give you access to host automation and MIDI control. Refer to [Macros](#).
2. **Browser**: Lets you search and load presets from the factory library, your user library, and any installed Expansions. Refer to [Using the Browser](#).
3. **Remote Octave** (not available in Massive X Player): Special key zone with access to 12 optional variations of the Performers. Refer to [Remote Octave](#).

Using the Browser

The Browser contains the following features and controls:

1. **Product Filter:** Contains all your factory libraries and Expansions. Selecting a Product tile filters the Results list with relevant presets. Browsing with Filter tags and Text Search adjusts the Product filter accordingly. Refer to [Using filters](#).
2. **Tag Filters:** Contains Sound Type and Character filters that use NKS tagging to enhance the browsing experience. Switch between the two Filters interchangeably and explore tags that classify and organize presets based on various musical attributes and functions. Refer to [Using filters](#).
3. **Search field:** Filters presets according to the text entered in the Search field. The search engine considers preset names, author, filter names, and metadata including Character and Product tags. The Results list is filtered according to the terms entered in the Search field. Additionally, it shows your selection in the Sound Type and Character filters, and lets you remove filter tags. Refer to [Using the Search field](#).
4. **User Content:** Displays user presets in the Results list. Click the User icon to activate the filter and remove factory presets from your search. User presets will not be included in the Product and NKS tags, but can be added to the Favorites list. Refer to [Using presets](#).
5. **Favorites** (star icon): Filters presets in the Results list by Favorite tags. You can assign a Favorite tag to any preset in the Results list, creating quick access to a custom collection of your most beloved presets sounds. Refer to [Using Favorites](#).
6. **Results List:** Displays the list of presets according to the options set in the Search field, User presets, Favorites, and Filters. Presets are listed in alphabetical order and the selected preset is highlighted. Click the name of a preset to load it. You can also double-click the name to load the preset and directly switch back to the previous view in one go. When more than one page of presets is available, a scroll bar appears when hovering your mouse in the area below the Results list. Clicking + dragging the scroll bar moves through the presets. Additionally, you can scroll via your mouse wheel or touchpad. Refer to [Using filters](#).
7. **Preset Count:** Displays the number of presets currently in the Results list. This useful feature allows you to monitor the affect of your filtering, highlighting the potential need for tag refinement to help narrow down extensive Results lists.

Using filters

Filters enable you to search for sounds using tags and Product tiles. Tags are used to characterize and classify presets based on various musical attributes. All presets in the Massive X library are tagged in a meaningful way to encourage your sonic exploration and help you find results quickly. Sound Type and Character filters use NKS tags to search for preset sounds. Selecting a Product tile will display only results contained in the respective product. All filters can be used in combination with the Search field to further refine your search results.

The Sound Type filter enables you to show results according to the types of instruments or sounds they are associated with. Selecting a tag will automatically amend the tag list with related NKS sub-tags, if available. The Character filter enables you to further refine your search by selecting various attributes and characteristics that can be used to describe the sound you are looking for.

When a tag is selected it is highlighted in the tagging area and the Results list is updated accordingly. A single click adds the selected tag, whilst removing all other tags. Pressing [command] (macOS) or [Ctrl] (Windows) and clicking selects multiple tags.

You can hide the Sound Type and Character filters by clicking the arrow icon in the upper right corner of the filter area.

To browse for presets using Sound Type and Character Filter tags:

1. Click a Filter category (Sound Type or Character) to open it and show the contained Filter tags.

2. Click a Filter tag to start filtering the presets in the Results list.

3. Click the other Filter category to open it and display the contained Filter tags. The first Filter closes automatically, though its selected tags remain active.

4. Click a Filter tag to continue filtering the presets in the Results list.

- Press [command] (macOS) or [Ctrl] (Windows) + click to select another Filter tag from the same Filter type and further add to the filtered presets.

- The presets in the Results list are filtered by the selected tags. Only presets containing any of the selected Filter tags are shown.

i Your selection in the Sound Type and Character filters is shown in the Search field, which also allows you to remove them from your search. For more information, refer to [Using the Search field](#).

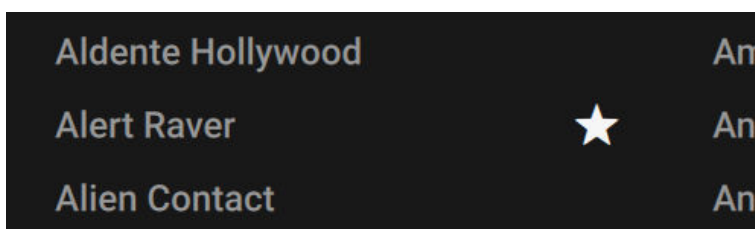

Using Favorites

Favorites enable you to tag your most frequently used and enjoyed presets, and recall them at any time. By assigning Favorite tags to presets in the Results list you can create a personal collection of sounds that can be easily accessed from the Browser. Favorites can be used for both factory and user presets. Favorite preset files are shared between Massive X, Maschine, and Komplete Kontrol.

- To assign a Favorite tag, click the star icon that appears when a preset is selected or hovered over.

- The Favorite tag is assigned. Clicking the star again removes the tag.

Once assigned, Favorites serve as an additional filter in the Browser. You can continue to use other filters to refine your search, including the search field.

- To view your Favorites in the Results list, click the Favorites icon in the search field.

- Only presets that have the Favorite tag assigned are shown in the Results list.

Using the Search field

The Search field at the top of the Browser interface allows you to filter presets with text entry. The search considers preset names, author, Filter titles, and metadata including Character and Product tags.

To filter presets using the Search field:

1. Activate the Search field by clicking it.

2. Enter your search terms.

- The Result list is filtered according to the terms entered in the Search field.

Your search entry remains in the field even when the Browser is closed.

- To clear the search, click the cross icon on the right side of the Search field.

If you are browsing using the Sound Type and Character filters, your search will only display results matching both the selected tags and your search terms. The Search field shows all selected filter tags, and lets you remove them from your search:

- ▶ To remove a specific filter tag from your search, click its name in the Search field.
- ▶ To remove all filter tags from your search, click **Reset** in the Search field.

Using presets

Massive X contains an expansive range of dynamic preset sounds that are accessed and managed in the Browser. Searching for presets using the Browser's extended filtering and tagging options allows you to hone in on your specific sonic needs, whilst facilitating the discovery of new sound spectrums.

Loading a preset

Presets can be loaded one-by-one directly from the Header or selected within the Browser. Using the browse arrows in the Header, you can quickly step through the presets from within the selected category. Using the Browser, you can access an overview of all categories to search and load presets.

To load a preset from the Header:

1. Click the up arrow to step upwards through the selected category of presets.
2. Click the down arrow to step downwards through the selected category of presets.

→ The preset will load immediately each time an arrow is pressed.

.

To load a preset from the Browser:

1. Click either the magnifying glass icon, the category, or the current preset name in the Header.
2. When the Browser opens, select a category from the list on the left. If you require access to your saved presets, select the User category.
3. Select a preset name from the list on the right.

→ The selected preset will be loaded.

Saving a preset

Saving presets allows you to work on custom sounds and recall them at a later time. When you create a sound you like, you can save it as a User preset and it will be added to the User Presets folder on your computer, and displayed in the **User** category of the Massive X Browser.

To save a preset to the User folder:

1. Click the Save button (disk icon) in the Header.
2. In the dialog that appears, enter a name for your preset.
3. Optionally, enter the name of the author who created the preset. The default name is Native Instruments.

4. Click **Save** to store the preset.
- If the preset name you provided already exists in the User category, you will be prompted with the option to replace your existing preset.
5. Click **Replace** if you want to replace it, or provide a new name for your preset
6. Click **Save**. You can also select **Cancel** at any time to exit the procedure.
- The preset file is saved to the User Preset Library. It appears in the **User** category in the Browser .

 You can not overwrite presets in the Massive X Factory Library. If you decide to edit a Factory Library preset and save it, it will be stored as a separate preset in the User category.

 If you delete any files in the User Presets folder, you must rescan your sounds by selecting **Rescan Content** in the Settings menu. Only after rescanning your content will the list of presets in the Browser be updated. For more information, refer to [Managing user presets](#).

Importing a preset

Presets can be imported into the User Presets folder by dropping the preset files onto the Massive X user interface. A preset file can be dropped anywhere on the user interface and it will automatically be saved to the User Presets folder and accessed in the User category in the Browser.

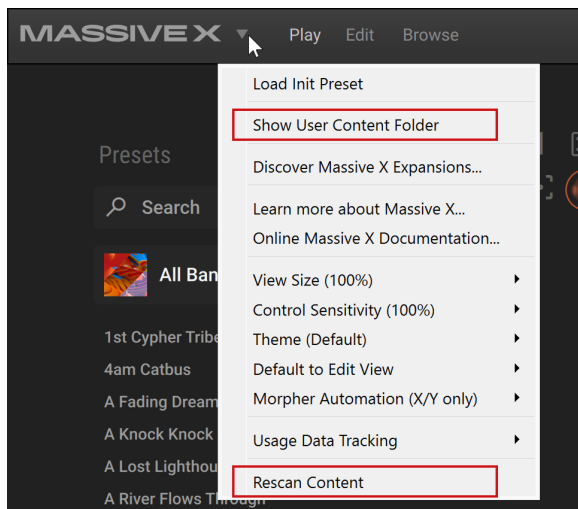

To import a preset file to the User Presets folder:

1. Select the preset file on your hard drive you want to import.
2. Drag and drop the file onto the Massive X user interface.
- The preset file is now saved into the User Presets folder.

 New content must be scanned, otherwise, it will not appear in the Browser. To scan new content, either relaunch the application or manually trigger **Rescan Content** from the Settings menu in the Header.

Managing user presets

The Settings menu provides two options to help you manage your user presets: **Show User Content Folder** and **Rescan Content**.

Accessing user presets

To view, add, or delete your preset files:

1. Open the Settings menu, located next to the Massive X logo on the left side of the Header.
2. Click **Show User Content Folder**.
3. Use the Presets folder to view, add, or delete your user preset files.
4. When finished, rescan content to update the Browser with any changes made.

Rescanning user presets

When a preset has been added or deleted, you must rescan the user presets folder to reflect these changes in the Browser.

To rescan for user presets:

1. Open the Settings menu, located next to the Massive X logo on the left side of the Header.
2. Click **Rescan Content**.

→ The Browser is updated to reflect the files in the User Presets folder.

From version 1.3.1 onwards, all new user presets are stored in a dedicated *Presets* subfolder in the user content directory, located on your computer: *Documents/Native Instruments/User Content/Massive X/Presets*. User presets from earlier versions will still be read from the folder: *User Content/Massive X*.

6. Macros

Massive X includes a number of global control sources called **Macros** that you can use to interact with your sound. Depending on their assignments in the loaded preset, the Modulation wheel, Pitch Bend wheel, Aftertouch control, and the 16 Macro knobs let you quickly access specific parameters or control multiple parameters from a single Macro. In the full version of Massive X, you can change their assignments.

You can control the Modulation wheel, Pitch Bend wheel, Aftertouch control, and the 16 Macro knobs from a MIDI keyboard/controller or using host automation in your DAW. This allows you to automate any Massive X parameter that is assigned to a Macro.

i You can also control the [Morpher cursor](#) from a MIDI keyboard or using host automation.

In Massive X Player, all the Macros are visible in the **Macro bar** at the top of the [Browse view](#). You cannot change the Macro assignments nor labels.

In the full version of Massive X, all the Macros are visible in the **Macro bar** at the top of the [Browse view](#) and [Edit view](#). You can modify the Macro assignments in the Edit view and change their labels in the Edit and Browse views.

i The first eight Macros 1–8 are also available in the [Play view](#).

The Macro bar contains the following elements:

1. **PB (Pitch Bend)**: A standard MIDI control found on any keyboard controller, often in the form of a spring-loaded wheel.
2. **M (Modulation)**: A standard MIDI control found on most keyboard controllers, often in the form of a freely adjustable wheel.
3. **AT (Aftertouch)**: A special MIDI expression found on many keyboard controllers, transmitting the amount of pressure applied to the pressed keys.
4. **Animator on/off switch**: Activates or deactivates the [Animator](#) in the Play view. This mirrors the **Animator** on/off switch available in the Play view.
5. **1–16 (Macro knobs)**: Continuous controls that can be used as shortcuts for parameters.

Except for the Animator on/off switch, all the controls of the Macro bar are red when they are assigned, and white otherwise.

Assigning Macros to single parameters

i This feature is not available in Massive X Player.

The Macros can take over the full range of a single parameter, which is called a **1:1 mapping**.

For example, you can use the modulation wheel to control the Wavetable Position.

- Drag and drop the modulation wheel icon (**M**) from the Header onto the Wavetable Position knob.

- The Wavetable Position is now controlled by moving the modulation wheel on your keyboard controller.

For information about removing Macro assignments, refer to [Removing and muting Macros](#).

Assigning Macros to multiple parameters

This feature is not available in Massive X Player.

The Macros can adjust multiple parameters at the same time, and to a varying degree.

For example, you can use Macro **1** to control both the Wavetable Position and the Wavetable's **Filter** parameters:

1. Drag and drop the Macro icon (1) from the Header onto the first modulation slot of the Wavetable Position control.

- The Macro label 1 appears in the first modulation slot to indicate the assignment.
2. Click and drag this modulation slot vertically to adjust the modulation amount.

- On the Wavetable Position knob, a colored segment around the current knob position indicates the modulation amount.

3. Drag and drop the Macro icon (1) from the Header onto the first modulation slot of the Wavetable's **Filter** control.

- The Macro label **1** appears in the first modulation slot to indicate the assignment.
4. Click and drag this modulation slot vertically to adjust the modulation amount.

- By playing a note and turning Macro **1** you can now control the two parameters of the Wavetable oscillator at the same time.

For information about removing or muting Macro assignments, refer to [Removing and muting Macros](#).

Replacing Macros

This feature is not available in Massive X Player.

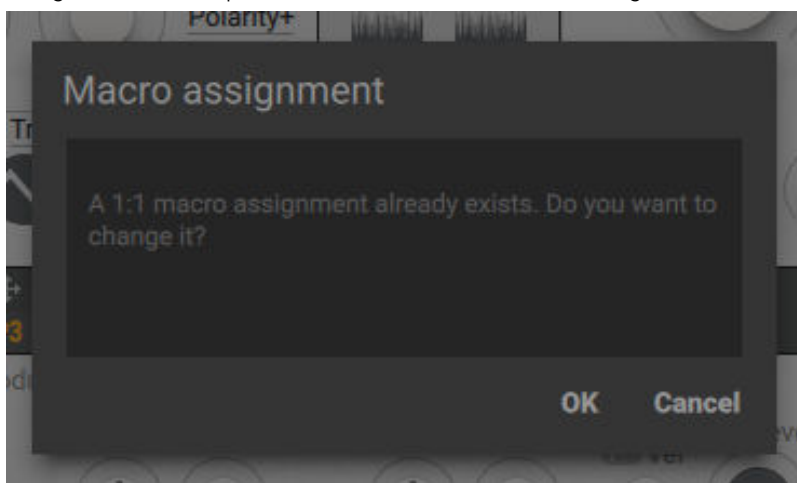

In some scenarios, you might want to remove a 1:1 Macro assignment and instead assign the Macro to a modulation slot of the same parameter, or vice versa.

To replace a 1:1 Macro assignment for a parameter with a modulation slot assignment:

1. Drag and drop the Macro icon from the Header onto the modulation slot.

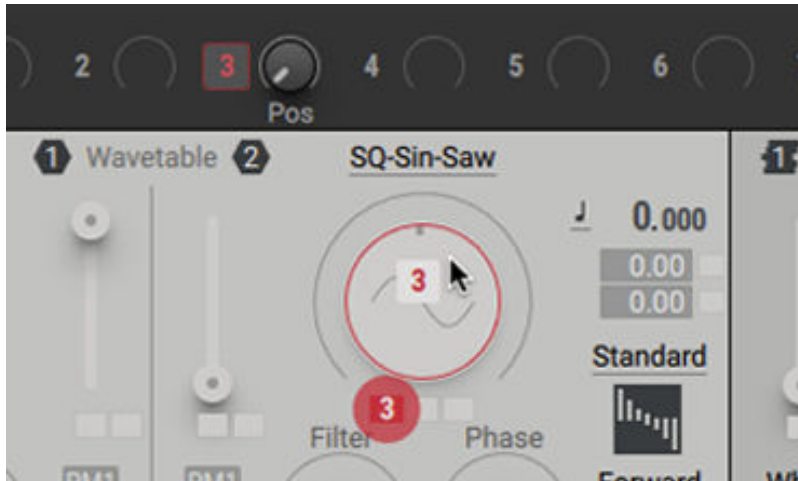

2. A dialog box appears, asking you to confirm the change. Click **OK** to remove the 1:1 Macro assignment, and replace it with a modulation slot assignment.

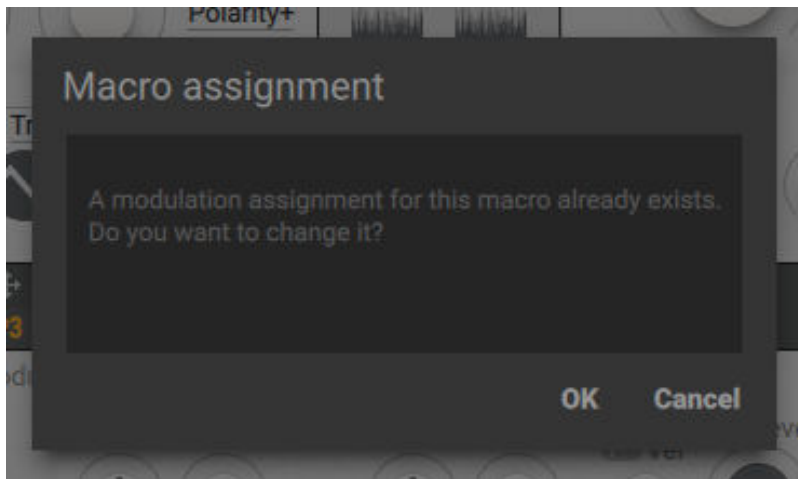

To replace a modulation slot assignment for a parameter with with a 1:1 Macro assignment:

1. Drag and drop the Macro icon from the Header onto the parameter's control.

2. A dialog box appears, asking you to confirm the change. Click **OK** to remove the Macro's modulation slot assignment, and replace it with a 1:1 Macro assignment.

Removing and muting Macros

 This feature is not available in Massive X Player.

You can remove or mute Macro assignments using the context menu for each Macro by right-clicking the Macro number.

Removing single assignment

To remove a Macro assignment from a single parameter:

1. Right-click the Macro number left of the Macro knob.

2. Select **Remove 1:1 mapping**.

→ The assignment is removed and the Macro control is blank.

Removing or muting multiple assignments

When a Macro is assigned to multiple parameters, you can remove all assignments at once as follows:

1. Right-click the Macro number left of the Macro knob.

2. Select **Remove all modulations**.

→ The assignments are removed and the Macro control is blank.

When a Macro is assigned to multiple parameters, you can temporarily mute its assignments without removing them. For example, this is useful to make a quick A/B comparison for your modulation assignments.

To mute the Macro assignments:

1. Right-click the Macro number left of the Macro knob.
2. Select **Mute all connections**.

→ The assignments are now muted.

You can unmute the Macro assignments by using the same procedure.

Renaming Macros

i This feature is not available in Massive X Player.

The Macros are automatically named when they are assigned to a parameter. In some instances, for example, when multiple parameters are assigned to the same Macro, you may want to rename the Macro to represent the full functionality of the control.

To rename a Macro control:

1. Double-click the label under the Macro control to highlight it.

→ The label text is selected and can be edited.

2. Type the new Macro name in the text field and press [Enter] to confirm.

7. Edit view

Massive X's **Edit view** lets you adjust every detail of your sound.

 The Edit view is not available in Massive X Player.

► Click **Edit** in the Header to open the Edit view.

The Edit view groups related modules and functions in horizontal sections:

1. **Macro bar:** The Macros let you assign shortcuts to the desired parameters in Massive X. They also give you access to host automation and MIDI control. Refer to [Macros](#).

2. **Module panels:** Controls the generators and processors that are used to create your sound. You can freely connect them in the Routing page to achieve a wide range of synthesis techniques. This section includes:
 - **Global Tune:** Access the global tuning and glide settings. Adjust the tuning in semitones and cents and enable the glide effect (portamento). Refer to [Global Tune](#).
 - **Oscillators:** Work with two Wavetable oscillators that form the basis for sound generation in Massive X. Explore the collection of wavetables, different Modes of operation, and available controls. Refer to [Wavetable oscillators](#).
 - **Noise:** Use the two noise sources and the custom collection of noise samples to create dramatic textures, percussive elements, and random control voltages. Refer to [Noise](#).
 - **Filter:** Select from nine different types of filters that cover a wide range of applications. Balance and correct the tone of a sound, sculpt complex textures, and transform a patch entirely. Refer to [Filter](#).
 - **Insert Effects:** The three Insert Effects slots can be loaded with a range of effects modules, including distortion, sample and hold, and various insert oscillators. Refer to [Insert effects](#).
 - **Amplifier:** Control the level and panning of your signal before it enters the Stereo Effects section and adjust the feedback amount of the voice's feedback loop. Refer to [Amplifier](#).
 - **Stereo Effects:** Select from a range of time-based, utility, spatial, and saturation effects, with three available effects slots and three different routing options. Refer to [Stereo effects](#).
3. **Navigation Bar:** Selects the page you want to view in the editor. The available pages include Voice, Routing, and modulation sources. This section includes:
 - **Modulation:** From the navigation bar, you can assign modulation sources to controls by using drag and drop. Refer to [Modulation](#).
4. **Editor:** By selecting an editor page in the navigation bar, you can access all the controls and menus of the respective feature. Set monophonic or polyphonic behavior as well as unison and harmonizing on the Voice page, arrange and connect audio modules on the Routing page, or dive deep into any of the modulation sources. This section includes:
 - **Voice page:** Refer to [Voice page](#).
 - **Routing page:** Refer to [Routing](#).
 - **Modulation sources:** Refer to [Modulation sources](#).
5. **Remote Octave:** Control the contents of the Performers via MIDI. This way you can control the Performers' complex modulation curves in a playable manner and structure your song. This section includes:
 - **Remote Octave:** Refer to [Remote Octave](#).

Basic concepts

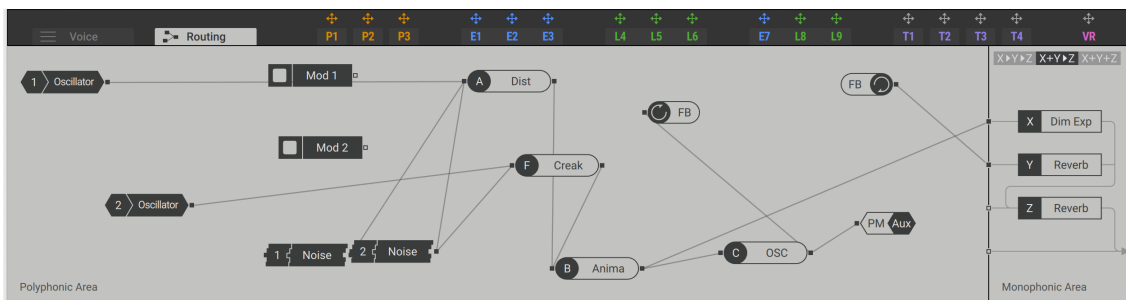

This section introduces basic concepts and key features that are fundamental to Massive X.

A **voice** consists of all components required by a synthesizer to create the sound of a single note. Massive X is a polyphonic instrument, meaning that it can play multiple voices at the same time. In basic polyphonic operation, each voice corresponds to a note event. For example, when playing a triad chord, three voices will sound simultaneously. Each voice is processed independently, so every note can have different movements and articulation in the sound.

On the Voice page, you can define how the instrument responds to note events and how they are allocated to the available voices. Expanding on these basic options, advanced **Unison** and **Scale** features make it possible to use the voices as tonal clusters and to form complex chords. For more information, refer to [Voice page](#).

Routing enables you to create or change the signal path of a synthesizer. In Massive X, you can freely route signals between the individual components of a voice, including sound generators and processors. This modular signal path facilitates a wide range of different synthesis techniques, giving you the freedom to design and explore sounds without constraints. You can use and combine techniques like wavetable synthesis, FM synthesis, subtractive synthesis, physical modeling, and various types of waveshaping, or distortion.

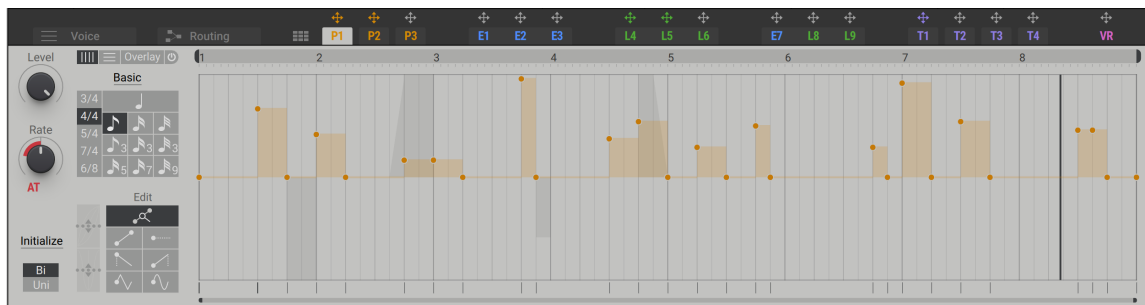

On the Routing page, you can define the structure of the voice in the **Polyphonic Area**, which contains modules like the Wavetable Oscillators, the Filter, and the Insert Effects. All polyphonic voices are summed and sent to the **Monophonic Area** with three additional Stereo Effects. For more information, refer to [Routing](#).

Massive X puts a strong focus on the concept of **modulation** by combining sophisticated modulation sources with an intuitive system for modulation assignment. Modulation adds movement to your sound by changing controls over time. This movement defines the character and expression of a sound as you play it, from the contour of its amplitude, or volume level, to its timbral qualities.

You can apply modulation sources to any number of parameters directly in the user interface by using drag and drop. Color-coded rings or lines next to controls indicate the modulation source and the amount of modulation applied to the parameter. For more information, refer to [Modulation](#).

Among the available modulation sources are the three **Performers**, which are specialized sequencers for modulation. They provide a flexible way to apply complex, rhythmical movements to parameters. The Performers can be controlled using the Remote Octave, which allows you to switch between patterns remotely using MIDI notes as key switches, or by selecting one of the 12 patterns using the mouse in the footer of Massive X.

The Performer's patterns and additional settings can be changed in the Editor by selecting the tabs labeled **P1**, **P2**, and **P3** in the navigation bar. From there, you can also open the Performer Grid view that provides an overview of all available patterns and their assignment to the Remote Octave. For more information, refer to [Performers](#) and [Remote Octave](#).

As additional control sources, Massive X provides a set of 19 **Macros** including pitch bend wheel, modulation wheel, and aftertouch controls as well as 16 Macro knobs. Each Macro can either take over the full range of a single parameter or control any number of parameters to a varying degree. Also, the Macros themselves can be controlled using MIDI and host automation from your DAW.

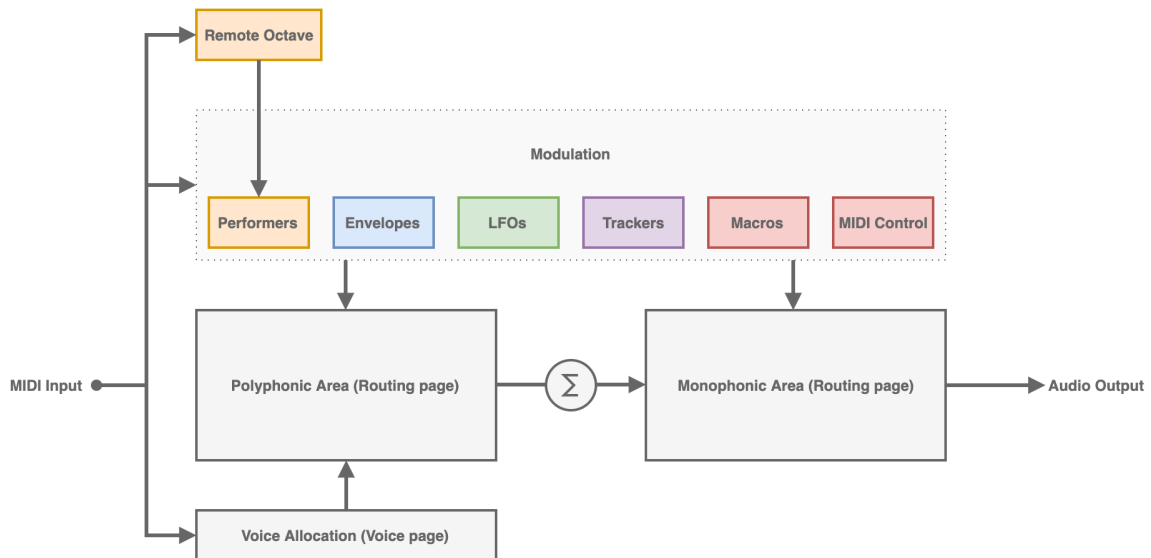

You can assign Macros to any number of parameters directly in the user interface by using drag and drop. Red rings or lines next to controls indicate the Macro assignment and its amount. For more information, refer to [Macros](#).

Instrument structure

Massive X is built on an advanced structure that facilitates a high degree of modularity while also enabling optimized signal processing. It is comprised of both polyphonic and monophonic components:

- Polyphonic components are processed independently for every single voice you play.
- Monophonic components are globally applied to the sum of all polyphonic voices.

The following diagram shows the types of components according to their structural relationships:

The **Polyphonic Area** contains the modular signal path of the polyphonic voices. It includes a variety of sound generators and processors that you can freely arrange and connect on the Routing page. For more information, refer to [Routing](#).

The **Monophonic Area** contains the effect chain that is globally applied to the sum of all polyphonic voices. It includes three stereo effects that you can use to process the output of the Polyphonic Area on the Routing page. For more information, refer to [Routing](#).

Modulation consists of various modulation sources and Macros that can be assigned to parameters across the instrument using the unified modulation system. Modulation sources can be monophonic or polyphonic, depending on their type and selected mode, as well as the parameter they are assigned to. Most modulation sources respond to incoming MIDI notes. For example, note events are used to trigger envelopes and reset LFOs. For more information, refer to [Modulation](#) and [Modulators](#). In addition, all the continuous parameters (typically in the form of rotary knobs) are available for host automation and MIDI control from your DAW.

Voice allocation distributes the incoming MIDI notes across the available polyphonic voices. On the Voice page, you can manage the behavior of the voices, or transform the MIDI notes to create complex voicings and harmonic layers. For more information, refer to [Voice page](#).

The **Remote Octave** provides dedicated control for the Performers, which are specialized sequencers for modulation. The Remote Octave maps incoming MIDI notes to key switches that you can use to access variations of the patterns used by the Performers. For more information, refer to [Remote Octave](#).

8. Modulation

i Editing modulation is not available in Massive X Player.

Modulation adds movement to your sound by changing controls over time. This movement defines the character and expression of a sound as you play it, from the contour of its amplitude, or volume level, to its timbral qualities. In technical terms, modulation is composed of slowly changing signals that cannot be heard directly. When you apply modulation to controls in your patch, the controls change their value according to the shape of the modulation signal.

Massive X puts a strong focus on the concept of modulation by combining sophisticated modulation sources with an intuitive system for modulation assignment: modulation sources can be applied to any number of parameters using drag and drop, and the modulation assignments are visualized directly in the user interface. Color-coded rings or lines next to controls show not only which type of source is used, but also the amount of modulation applied to the parameter.

Modulation overview

The following key elements and controls are used for modulation in Massive X:

- 1. Modulation Sources:** Access all available modulation sources from the navigation bar. You can display them in the Editor in groups of three by clicking on their labels (e.g. **P1**, **E2**, **L8**, **T3**). For more information, refer to [Modulation sources](#).
- 2. Modulator Menu:** Select from four available Modulators (Modulation Envelope, Excited Envelope, Switcher LFO, Random LFO). You can load one Modulator for each of the blue and green modulation sources in the navigation bar. For more information, refer to [Modulators](#).
- 3. Modulation Assign** (arrow cross icon): Assign modulation sources to parameters in Massive X. Drag and drop the assign icon onto a modulation slot, or click the assign icon and then select the modulation slot to assign a modulation source. For more information, refer to [Assigning modulation](#).
- 4. Modulation Slot:** Displays and controls the modulation assignment for the corresponding parameter. Two modulation slots are available for each parameter (left and right slot beneath a control). When a modulation source is assigned, clicking and dragging the modulation slot up and down adjusts the modulation amount as displayed by the color-coded ring or line next to the control. For more information, refer to [Assigning modulation](#).

5. **Sidechain Modulation Slot:** Assign a modulation source for sidechain modulation. Sidechain modulation controls the amount of modulation applied to the slots left and right. The sidechain modulation slot can also be used like a regular modulation slot. For more information, refer to [Sidechain modulation](#).
6. **Sidechain Modulation Amount:** Adjust the amount of sidechain modulation applied to the corresponding modulation slot from the sidechain modulation slot. For more information, refer to [Sidechain modulation](#).
7. **Modulation Amount:** Adjust the amount of modulation applied to the parameter from the modulation source. The modulation amount is represented by a color-coded ring or line next to the control. For more information, refer to [Assigning modulation](#).
8. **Modulation Slot Menu:** Open this context menu by right-clicking a modulation slot. Use it to delete the modulation assignment for this modulation slot.
9. **Modulation Source Menu:** Open this context menu by right-clicking a modulation source in the navigation bar. Use it to mute or delete all modulation assignments for the selected modulation source.

Modulation sources

Massive X provides a comprehensive set of modulation sources that can be used to add movement to your sound. All modulation sources can be assigned and accessed from the navigation bar:

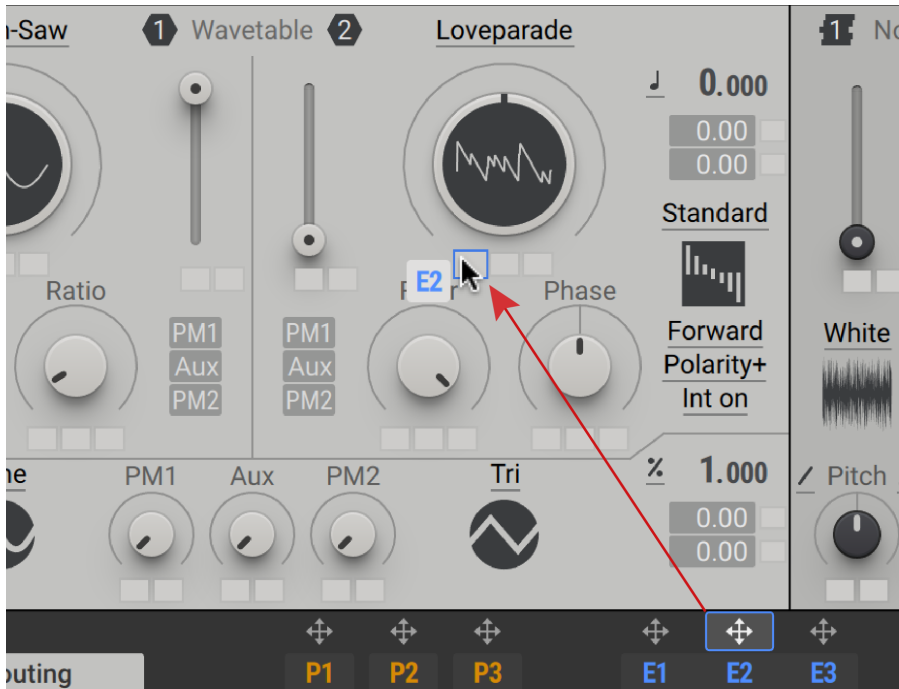

1. **Performers:** The three Performers are specialized sequencers for modulation. They provide a flexible way to apply complex, rhythmical movement to a range of parameters in Massive X. For more information, refer to [Performers](#).
2. **Modulators:** The four Modulators include a **Modulation Envelope**, an **Exciter Envelope** for physical modeling, a **Switcher LFO** for periodic modulation, and a **Random LFO** for randomized effects. Modulators can be loaded to any of the eight available slots, with **E1** hard-wired to control the Amplifier level. For more information, refer to [Modulators](#).
3. **Trackers:** The four Trackers provide deep functionality for advanced keyboard tracking. They map incoming MIDI control data to modulation that you can apply to any parameter. This enables you to define exactly how your sound responds to MIDI input. For more information, refer to [Trackers](#).
4. **Voice Randomization:** The Voice Randomization feature allows you to add pseudo-random variation to your sound, with results ranging from subtle differences in tuning to dramatic voicing effects. For more information, refer to [Voice Randomization](#).

Assigning modulation

Before the effect of the envelope or LFO can be heard, it must first be assigned to a parameter's modulation slot. Modulation sources can be assigned to multiple parameters at once, and the process for assigning each is the same. For information on removing and replacing Modulation assignments, refer to [Removing and replacing modulation](#).

To assign a modulation source to a parameter:

1. Drag and drop the arrow cross icon of a modulation source to a modulation slot. Alternatively, click the arrow cross icon and then select the modulation slot to make the assignment.
- Alternatively, click the arrow cross icon and then select the modulation slot to make the assignment.

2. Click and drag the modulation slot upwards or downwards to increase the modulation amount applied to the parameter. Dragging the slot upwards applies positive (non-inverted) modulation, and dragging the slot downwards applies negative (inverted) modulation.

- The modulation source is assigned and applied to the selected parameter.

You can double-click the modulation slot to set the maximum modulation amount or reset the amount to zero.

Removing and replacing modulation

You can remove or replace the modulation assignment of any modulation slot while retaining the modulation amount that has been set. When assigning a new modulation source, the original modulation amount is taken over.

To remove a modulation assignment:

1. Right-click the modulation slot.
2. Select **Delete**.

To replace a modulation assignment with another:

- Drag and drop the new modulation source onto the already assigned modulation slot.

Alternatively, you can first click the arrow icon and then the modulation slot to make an assignment.

Sidechain modulation

Sidechain modulation allows you to add movement to the modulation amount, or strength, of other modulation assignments. Instead of modulating the parameter itself, it changes the intensity of how another modulation source is applied to the parameter.

Sidechain modulation is facilitated by the following two key elements:

1. **Sidechain Modulation Slot:** Used to assign a modulation source for sidechain modulation, which can be applied to the modulation slots to the left and to the right. It is located in the middle of the three modulation slots. It can also be used for direct modulation of the parameter like a regular modulation slot.
2. **Sidechain Modulation Amount:** Used to adjust the amount of sidechain modulation applied to the corresponding modulation slot from the sidechain modulation slot.

In technical terms, the signal produced by the modulation source assigned to a modulation slot is multiplied by the signal produced by the modulation source assigned to the corresponding sidechain modulation slot, by a factor set with the sidechain modulation amount control.

9. Voice page

i This feature is not available in Massive X Player.

The Voice page offers control over a range of parameters relating to voice setup and polyphony within Massive X. Unison enables you to play several internal voices on top of one incoming note, and further controls allow you to modify these additional voices, producing powerful musical results. Voices can be detuned, stacked and spread to create a thicker, fuller, choir-like effect. Micro detuning can be used to recreate the often desired drifting and detuning qualities unique to analog synthesizers.

The Harmonizer section uses the additional voices to create harmonies, as determined by the selected Harmonization/Chord set. Modulating these parameters offers great creative potential, enabling you to explore different harmonies and create bold transitions. Whether you are creating thicker, stacked sounds or chord-structures, the Voice page is a powerful tool to explore the full potential of the Massive X synth engine.

Global Tune

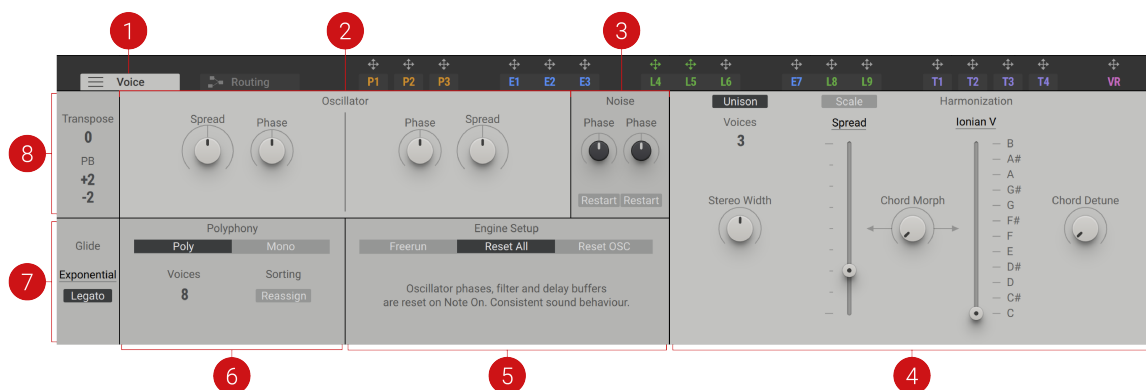

In this section, you can determine the global tuning and glide settings. The Tune parameter adjusts Massive X's tuning in semitones and cents. The **Glide** button enables the glide effect (portamento), which has further options for customization in the Polyphony section of the Voice page. For more information on glide, refer to [Glide](#).

1. **Tune:** Determines the global tuning of the oscillators in semitones and cents, from -64.000 to +64.000. The pitch can be modulated by routing a modulation source to either of the two modulation slots below.
2. **Glide On/Off:** Activates or deactivates the glide effect.
3. **Glide Time:** Adjusts the time it takes to glide from the first note pitch to the following note pitch. When the knob is turned fully left, there is no glide and the pitch will jump suddenly to the next. As the knob is turned right, the glide time increases, making the transitions slower between notes.

Voice page overview

This section provides an overview of the Voice page.

1. **Voicing tab:** Opens the Voice page in the editor.
2. **Oscillator:** Controls the relative phase of the two oscillators, and the phase spreading of the added unison voices for both oscillators. For more information, refer to [Oscillator](#).
3. **Noise:** Determines the start position and restart behavior of the noise samples. For more information, refer to [Noise Engine](#).
4. **Unison:** Determines the unison play behavior of Massive X. For more information, refer to [Unison](#).
5. **Engine Setup:** The Engine Setup defines the Oscillator/Noise restart behavior and voice stealing approach. For more information, refer to [Engine Setup](#).
6. **Polyphony:** Defines the polyphony and playback behavior. For more information, refer to [Polyphony](#).
7. **Glide:** Features parameters related to the glide effect (portamento). For more information, refer to [Glide](#).
8. **Global Voicing:** Contains parameters that determine the global transposition and pitch-bend settings. For more information, refer to [Global Voicing](#).

Global Voicing

This section contains parameters that are related to the transposition, global pitch bend settings, and glide behavior. **Global PB** defines the way Massive X responds to your master keyboard's pitch bend wheel or corresponding MIDI controller. It provides controls for the upper and lower values of the pitch bend range when the pitch bend wheel of the master keyboard is at the maximum up or full down position. Use this feature to set the maximum amount of pitch bend that can be applied to your sound. Setting a down value higher than the up value will invert the action on your pitch bend wheel.

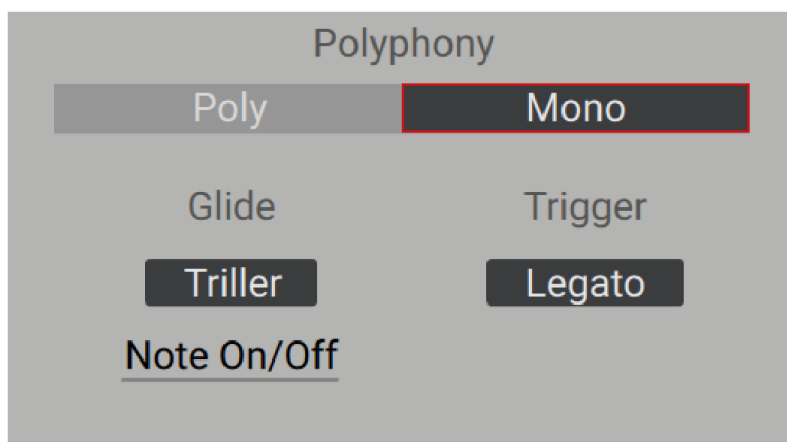

1. **Transpose:** Transposes the global pitch of the synthesizer in a range of -24 to +24 semitones (2 octaves).
2. **Global PB:** Determines the upper and lower values of the pitch bend control, in a range from -96 to +96 semitones.

Polyphony

This section allows you to define the polyphonic scheme of the Massive X synth engine, which operates in either **Mono** (monophonic) or **Poly** (polyphonic) mode.

Mono Mode

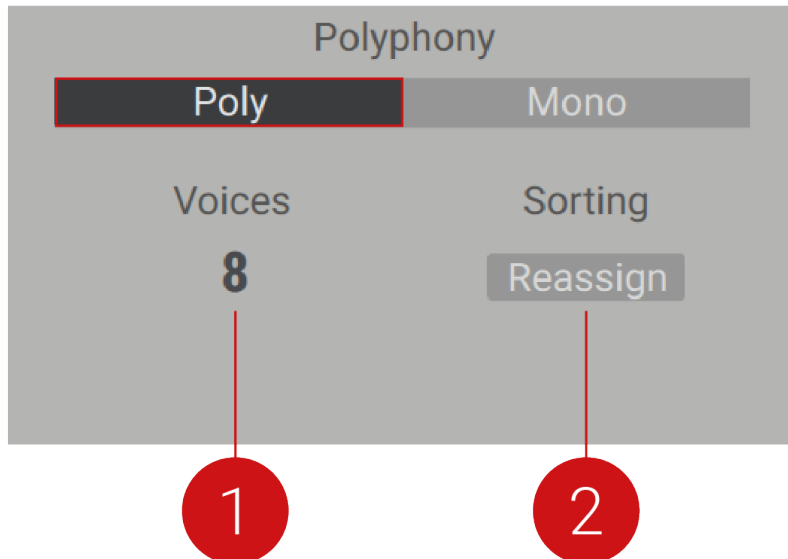

In **Mono** mode, only one note can be played at a time as with classic vintage monophonic synthesizers. However, unison voices can still be stacked on top of this note creating huge sounds or even harmonies.

To learn more about the controls available in **Mono** mode, refer to [Glide](#).

Poly Mode

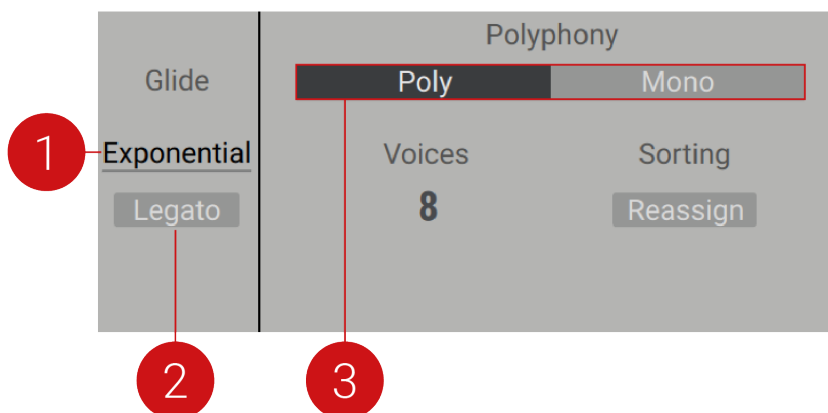

Poly mode allows to play up to 64 notes at a time. The maximum number of **Voices** is set in the **Poly** panel. This is not including the unison voices, which can be stacked on top of this. Keep in mind that a higher number of voices also leads to a higher CPU load.

1. **Voices:** Determines the maximum number of voices that can be played at the same time before voice stealing kicks in (1-64).
2. **Voice Sorting:** Selects between **Rotate** and **Reassign** modes. **Rotate** is the most common mode in polyphonic synthesizers. Each new note is distributed to a new voice ID. In this case, it's possible for two notes with the same pitch to be playing, a feature that is not possible with an acoustic instrument like piano or vibraphone. **Reassign** mode detects when you play the same note and allocates the same voice to the same note. This is good for piano and is particularly useful when you are trying to mimic acoustic behavior, as it won't cut off the pitch.

Glide

The Glide parameters determine the pitch transition between sequentially played notes, often called portamento. The **Glide** button and the **Glide Time** control are located on the upper left panel.

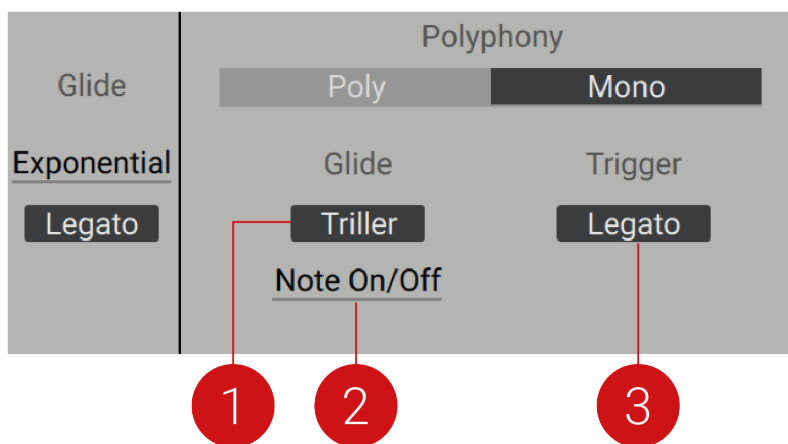

1. **Glide Shape:** Selects the style of glide transition (**Linear**, **Exponential**, **Inverse Exp**). A **Linear** setting creates a straight, even transition. **Exponential** produces the equivalent of an analog 1-pole low-pass filter curve. Typically, this is the best choice for classic glide. **Inverse Exp** flips the characteristics of the LP glide, a feature not possible using analog filters.

2. **Legato:** When active, the pitch glide only occurs when more than one note on the keyboard is pressed. When **Glide** is on and **Legato** is deactivated, a glide will always play on every note.
3. **Polyphony:** Selects the operating mode (**Mono**, **Poly**). In **Mono** mode, the glide time is a constant rate, and in **Poly** mode, it is constant time. The glide behavior and available controls differ depending on the mode selected. Change the mode by clicking on the tab.

Mono Mode

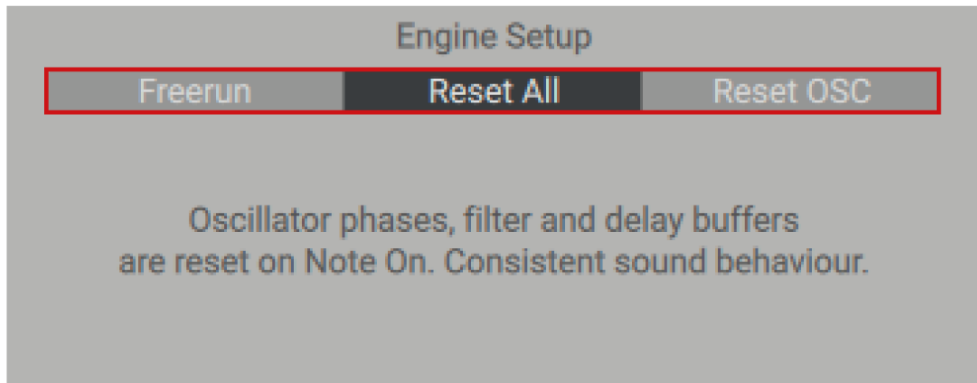

The following Glide parameters are only available if Massive X is operating in **Mono** mode:

1. **Triller:** Triller takes effect whenever a legato note is played, independent from the general **Legato** option. When active, Triller mimics the behavior you would typically find in a classic analog synth. If a legato note is released, the pitch glides back to the held note. When deactivated, all notes are killed when the legato note is released.
2. **Glide options:** Selects one of three options (**Note On**, **Note On/Off**, **Note Off**) that determines the glide behavior in response to MIDI. When **Note On** is selected, the glide only occurs when notes are pressed. When the key is released, the note pitch immediately falls back without gliding. When **Note Off** is selected, the glide only occurs when notes are released. **Note On/Off** triggers the glide when notes are pressed and released.
3. **Trigger Legato:** Determines the envelope restart behavior during legato play. When deactivated, the envelopes and LFOs restart every time a note is played. When active, the envelopes are not re-triggered during legato playing. If **Legato** and **Triller** are active in **Mono** mode, the Glide options menu is shown, with more detailed options for the pitch glide.

Engine Setup

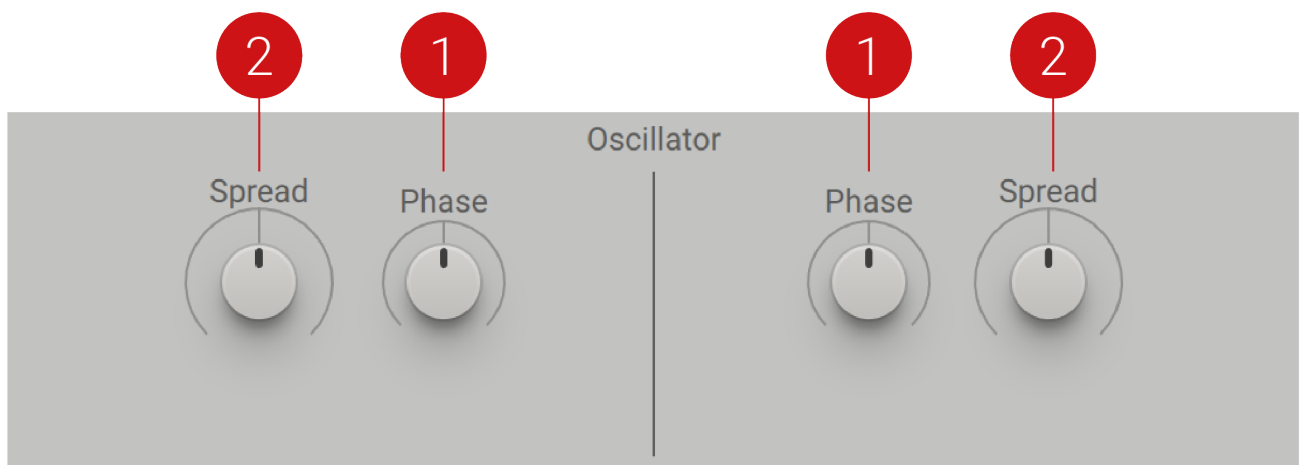

The Engine Setup section provides a selection of three modes (**Freerun**, **Reset All** and **Reset OSC**) that determine the reset behavior of the oscillator phases, filter, and delay buffers.

1. When **Reset OSC** is selected, the oscillator phases are restarted with each new incoming note.
2. **Reset All** adds resetting of the filter and delay buffers, for example, in the Comb filter and Track Delay. The benefit is consistent sound behavior, where the same note will always sound the same, for example, if a filter is self-oscillating with a maximum resonance setting, **Reset All** resets the filter and when a new note is played it will require time for the filter to build up self-oscillation again. In **Freerun**, the self-oscillation would prevail, as the oscillator and filter resetting is deactivated. **Freerun** is the traditional mode that aims to recreate analog oscillator and filter behavior.
3. In **Freerun**, the self-oscillation would prevail, as the oscillator and filter resetting is deactivated. **Freerun** is the traditional mode that aims to recreate analog oscillator and filter behavior.

Oscillator

This section becomes available if the Engine Setup is operating in **Reset All** or **Reset OSC** mode. It allows you to set the start phase of the two oscillators and the phase spread of the additional unison voices. For information about the Oscillators, refer to [Wavetable oscillators](#).

1. **Phase:** Adjusts the restart phase of the oscillator. In the middle position (0 degrees), the oscillator starts from the original phase. Turned fully left, the phase starts at -180 degrees and turned fully right, the phase starts at +180 degrees. Usually, the center position is used.
2. **Spread:** Spreads out the starting phases for the added unison voices. Turned fully left, all voices start at the same phase position with 0% Spread.

Noise Engine

This section is where you determine the playback mode of the noisetables, and control the *Phase* or *Start* position of the noise sources. For more information on the noisetables, refer to [Noise](#).

Three modes determine the playback of the noisetable. One Shot mode is well suited to noisetables found in the Transients category. In combination with this mode, they can produce powerful percussive sounds. Switching between modes will restore the *Phase/Start* value. One Shot mode applies a fade-out to any noisetables that have an abrupt rise in the sample that could result in an audio click.

The Noise Engine contains the following controls:

1. **Phase/Start:** Adjusts the phase/start position for each noise source, depending on the selected **Mode**. In **Free** mode and **Restart** mode, the control adjusts the **Phase** position of the sample playback from 0% to 100%. In **One Shot** mode, **Start** replaces the **Phase** control and adjusts the start position of the sample playback. The default value is 0%, meaning the one-shot sample will playback at its original position.
2. **Mode:** Selects one of three modes (Free, Restart, One Shot), that determines the playback behavior of the noisetable. **Free** is selected as default. In **Free** mode, the noisetable loops and runs freely. When **Restart** is selected, the noise source restarts at the set **Phase** position, each time a key is pressed. In **One Shot** mode, the sample plays through once only.

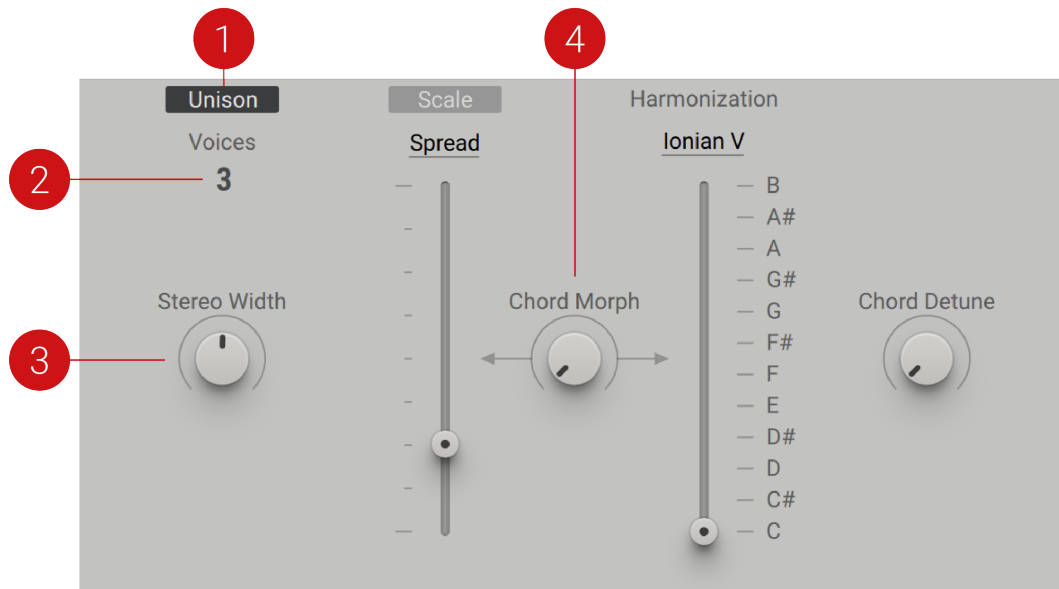

Unison

The Unison section can be used to fatten up and add life to your sounds. Additional voices with slightly different tunings can be used to recreate analog-style "beating", the sound of multiple oscillators drifting in and out of phase. On the other side of the spectrum, the Unison section can be used to create chords and harmonies on top of single notes played. The additional unison voices comprise the full voice architecture as set up in the Routing section and are not limited to just the oscillators.

The left fader is used for detuning, to create the traditional unison effect that makes your sound thicker. On the right is the Harmonization fader, which allows you to choose the key when in Harmonize mode or a chord set when in Chord mode.

The Unison section is where you can determine the internal structure of voices when triggered by one note from the MIDI keyboard. Grouping voices in different voice containers allows you to save notes, ensuring they can't be stolen. The idea of voices with voices inside comes from the inherent voicing limitations of analog and digital synthesizers, and the need to make use of all available voices.

The **Voices** parameter enables you to adjust the number of voices that will be played for each key that is pressed on the keyboard. When set to 1, only one voice will be played when a key is pressed and no unison effect will be heard. If the value is set higher, the corresponding number of voices will be triggered when a key is pressed. This stacking effect creates a thicker sound. Modifying the additional voices by spreading them across the stereo field creates a wider, fuller sound.

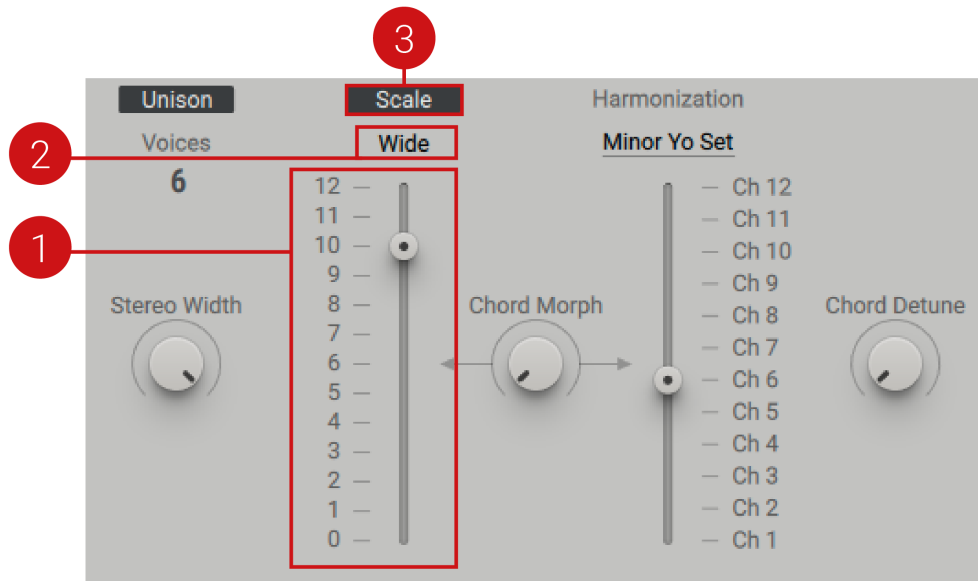

1. **Unison:** Activates or deactivates Unison mode. When on, the Unison section and all its related controls are available.
2. **Voices:** Sets the number of voices (1-6) for Unison mode. When **Voices** is set to 1, there is no unison effect.
3. **Stereo Width:** Adjusts the stereo spread of the voices. Turned fully left, all voices are centered mono. As the knob is turned right, the voices are spread in the stereo field.
4. **Chord Morph:** Morphs the tunings of the unison voices. This can create dramatic effects like the THX sound effect.

Detune

The left side of the Unison section is where you can set detuning, and control the stereo spreading of the added unison voices. The result is more typical of the classic unison sound.

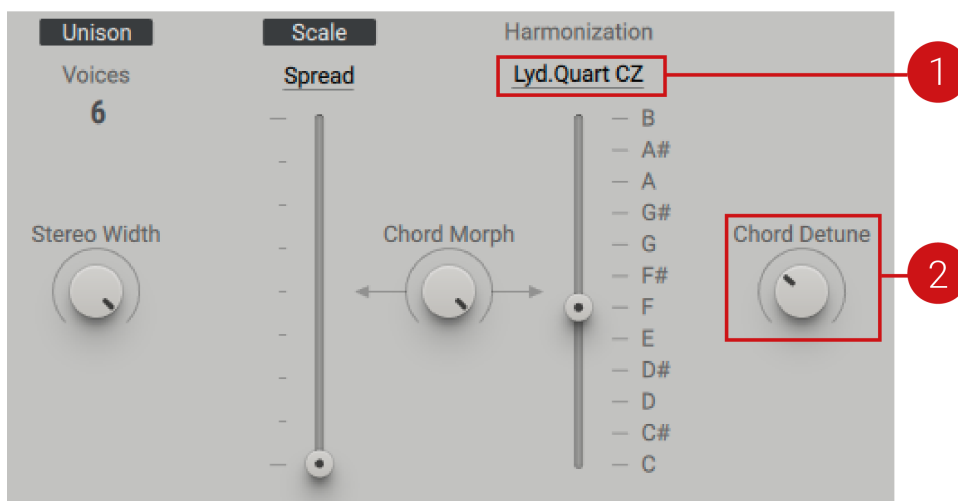

Spread and **Wide** tune modes can produce anything from slightly detuned moving timbres to musical intervals, creating a bigger, thicker sound. Through the inherent phase shifting of detuned oscillators sounding together, new timbres are produced. This is recreated in Massive X by detuning unison voices slightly to create a choir-like effect. The strength of the effect is determined by the amount of spread and detuning applied, as well as the number of voices available.

1. **Spread Fader:** Adjusts the general amount of unison detuning. In **Wide** mode the fader has a semitone scale. Click on a number within the scale to choose perfect semitone offsets.
2. **Spread Mode:** Selects from one of two modes (**Spread**, **Wide**) that determines the range of detuning. **Spread** mode is for micro detuning, and is fundamentally designed to make the signal sound more alive. Unequal spreading produces a less predictable sound. This effect can be properly heard with more than 3 voices and produces the best results when 4, 5, or 6 voices are selected. **Wide** mode offsets the tuning of unison voices by a maximum range of one octave. The equal distribution of the spreading produces a pattern in the beating that is more distinguishable. When **Wide** mode is selected the pitch can be shifted to a maximum of 1 octave.
3. **Scale:** When activated, the played voices are re-pitched according to the selected Harmonization set.

Harmonization

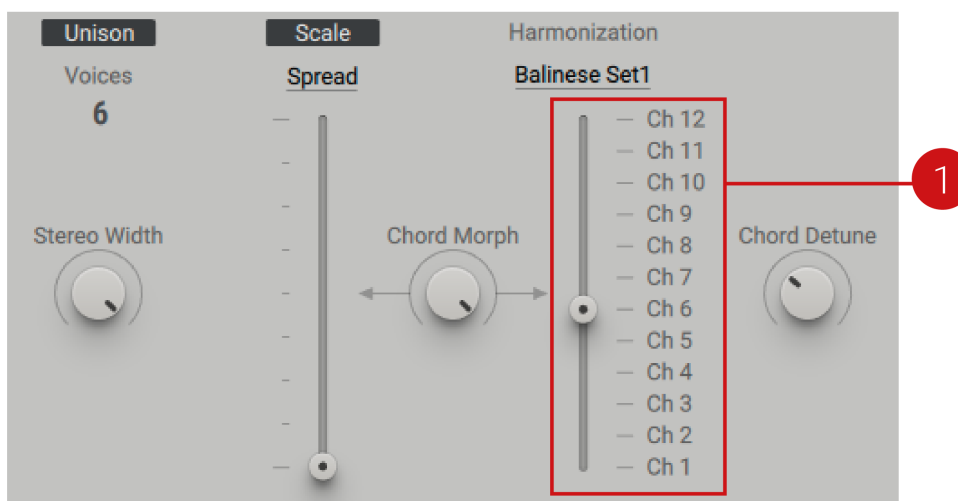

The Harmonization section allows you to build harmonies and perform within specific scales. Selecting between harmonize and chord modes will dictate the function of the right fader. In harmonize modes, the fader sets the key of the musical scale. In chord modes, different chord variations are stored across the fader.

1. **Harmonization Menu:** Selects between harmonize and chord modes. In harmonize modes the fader determines the root note. In chord modes, the fader is comprised of set intervals to create chords based on the number of selected voices.
2. **Chord Detune:** Slightly detunes the chord for a more pleasant or lively sound. Use the Tracker to control the chord and spreading.

Chord Modes

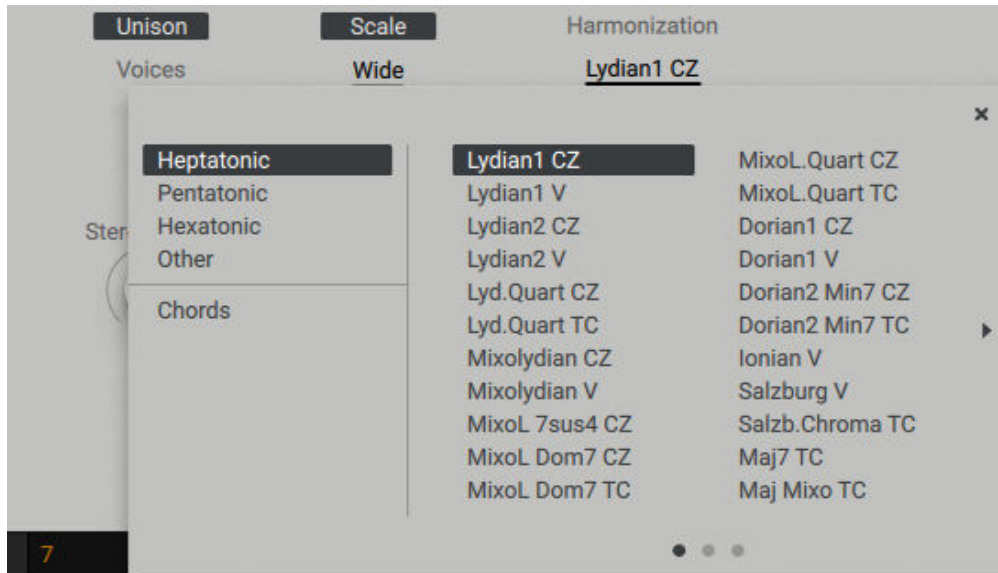

Chord modes enable you to play a variety of chords from a single MIDI note, providing parallel chords or transposition settings on top of the main pitch. When a chord mode is selected, the fader stores 12 variations of different chord settings. Adding the Performer to the chord fader allows you to tune through the different buffers, effectively jumping through your stored chords. The Tracker is another powerful option for modulation, allowing you to set the slider to an individual setting per note.

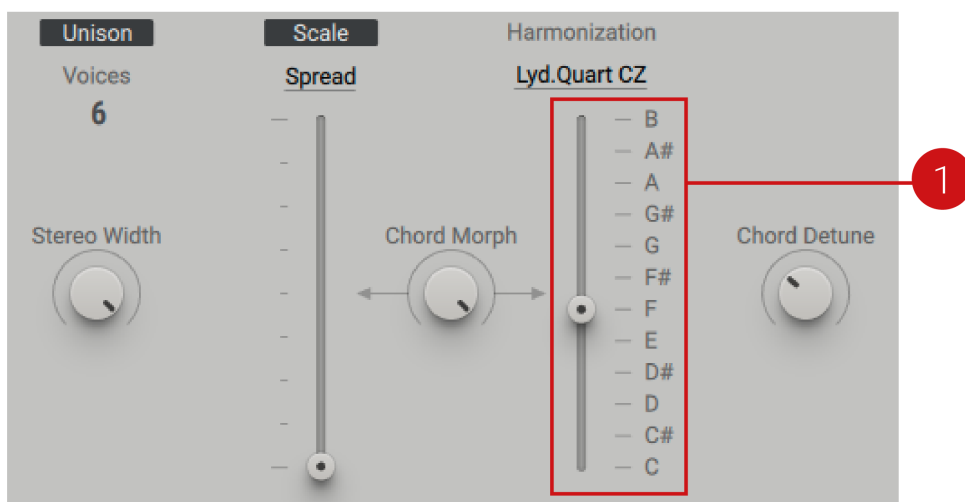

1. **Chord Slider:** Stores 12 variations of different chord settings.

Harmonize Modes

Harmonize modes allow you to select from a range of scales that determine the available set of notes from which you can build melodies and harmonies. Pitches from your MIDI device that are not within the set scale will be moved up or down, depending on the type of scale correction. Three settings determine the way scale correction is implemented; Catch Zone (**CZ**), Variation (**V**) and Transition (**TC**).

- **Catch Zone:** Corrects notes when a note is not within the specified scale. In sharp scales, the higher note will be corrected and moved down, for example, in the Lydian scale, C# becomes C. In flat scales, the correction is reversed and notes are moved up.
- **Variation:** Rearranges the chord structure instead of correcting the chord, using the free buffers for a new sound.
- **Transition:** Represents transitional chords, notable in classical music. Playing the transitional chords alone can produce undesired results as they are intended to be used to fill within the scale. The introduction of 4th chords leads to a more open sound.

1. **Harmonization Slider:** Determines the fundamental of the scale.

10. Routing

i This feature is not available in Massive X Player.

Massive X is a semi-modular synthesizer with an open architecture. This means you can freely arrange and connect its modules to facilitate a wide range of different synthesis techniques, giving you the freedom to design and explore sounds without constraints.

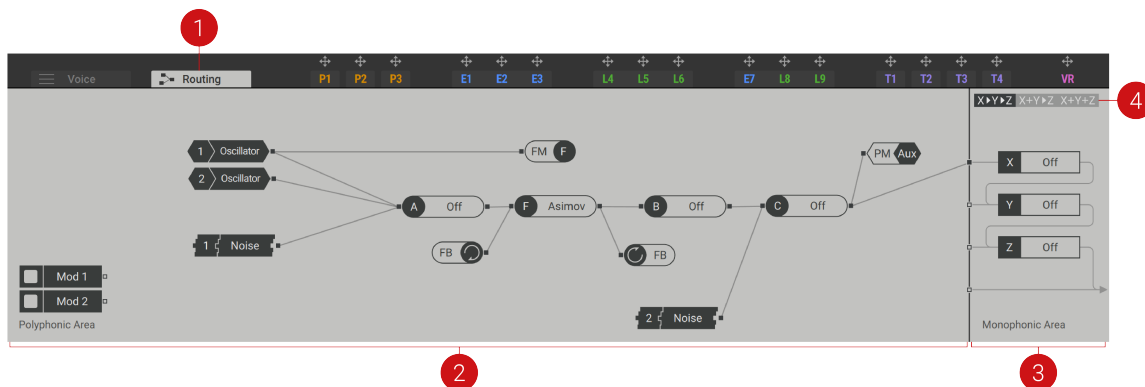

You can use and combine techniques like wavetable synthesis, phase modulation (PM, also called FM or frequency modulation), subtractive synthesis, physical modeling, and various types of waveshaping, or distortion. Modules are arranged and connected on the Routing page. Here you can combine all of Massive X's sound generators and processors to create your sound.

From the [Settings menu](#) in the Header you can quickly load the preset **Init - Massive X**, which offers a pre-configured routing as shown in the screenshot below (based on subtractive synthesis with Wavetable oscillators). This way you can immediately start creating sounds without having to make connections.

Routing page overview

The following overview shows the Routing page's two main areas, the *Polyphonic Area* and the *Monophonic Area*. The Polyphonic Area is used to define the signal path that is processed independently for every single voice you play. The Monophonic Area contains three Stereo Effects that are globally applied to the sum of all polyphonic voices.

1. **Routing Tab:** Opens the Routing page in the editor.

2. **Polyphonic Area:** Contains modules that you can use to define the signal path of the polyphonic voices. In order to complete the signal path, one or more module outputs need to be connected to the inputs of the Monophonic Area (2). The following modules can be found in the Polyphonic Area:
 - **Generators and processors:** The Oscillators, Noise sources, the Filter, and the Insert Effects are available in the Polyphonic Area. Black modules represent generators, gray modules represent processors. The icons shown on the modules can also be found on the corresponding module panel. For more information, refer to [Generators and processors](#).
 - **PM Aux bus:** Makes the phase modulation inputs of the Oscillators accessible in the routing. This way you can use any source in the signal path to apply phase modulation to the Wavetable oscillators and experiment with noise, feedback, and effects in this application. For more information, refer to [PM Aux bus](#).
 - **FB (Feedback) loop:** Makes the global feedback loop accessible in the routing. This way you can create a polyphonic feedback loop around modules to add chaotic and non-linear behavior. This feature is also useful for physical modeling sounds, especially when combined with the Comb filter. For more information, refer to [Feedback loop](#).
 - **Mod (Modulation) modules:** Any modulation source can be assigned to the Modulation modules by dragging and dropping. This way you can use the modulation sources as generators in the signal path. For example, you can use the Switcher LFO in OSC mode as an additional oscillator, or the Exciter Envelope as an exciter for the Comb filter. For more information, refer to [Modulation modules](#).
3. **Monophonic Area:** Sums the polyphonic voices and applies the three Stereo Effects X, Y, and Z before sending the output signal to the host. The Monophonic Area provides four inputs, one for each Stereo Effect as well as a single input that is directly sent to the host. For more information on the Stereo Effects, refer to [Stereo effects](#).
4. **Routing Options:** Three different routing options define the order of the effects in the signal path: **X > Y > Z** chains the three effects, **X + Y > Z** sends the sum of the X and Y effects to the Z effect, and **X + Y + Z** sums all three effects.

Generators and processors

The generators and processors available in the Polyphonic Area of the Routing page are the basic components you can use to build your sound. They consist of the Oscillators, Noise sources, the Filter, and the Insert Effects.

1. **Oscillators:** The Wavetable oscillators 1 and 2 are generators that each feature a single output. They can be connected to the processors and buses in the Polyphonic Area, or directly to an input of the Monophonic Area. For more information about the Oscillators, refer to [Wavetable oscillators](#).

2. **Noise sources:** The Noise sources 1 and 2 are generators that each feature a single output. They can be connected to the processors and buses in the Polyphonic Area, or directly to an input of the Monophonic Area. For more information about the Noise sources, refer to [Noise](#).
3. **Filter:** The Filter is a processor that features a single input and a single output. It can be connected to the generators, processors, and buses in the Polyphonic Area, or directly to an input of the Monophonic Area. The Filter types Asimov, Blue Monark, Groian, Scanner feature a special FM bus in the routing.

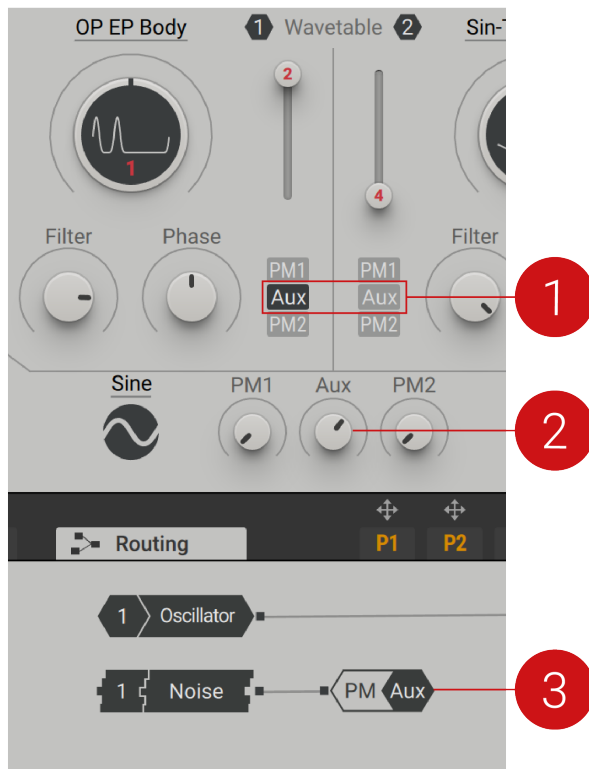

You can connect any source in the signal path here to apply audio rate modulation to the filter frequency, also called filter FM (frequency modulation). Filter FM produces rich harmonics and distortion effects. For more information about the Filter, refer to [Filter](#).

4. **Insert Effects:** The three Insert Effects (A, B, C) are processors that each feature a single input and a single output. They can be connected to the generators, processors, and buses in the Polyphonic Area, or directly to an input of the Monophonic Area. By selecting OSC or PM OSC for the Insert Effects, you can also use them as generators. For more information about the Insert Effects, refer to [Insert effects](#).

PM Aux bus

The PM Aux bus makes it possible to use any source in the signal path to apply phase modulation to the Wavetable oscillators. In this context, you can experiment with noise, feedback, and effects as the sources for phase modulation. For more information on using this technique and an overview of the PM Oscillators, refer to [Phase modulation](#).

The PM Aux bus has a dedicated module in the Polyphonic Area of the Routing page and additional controls on the panel of the Wavetable oscillators:

1. **Aux Assignment:** Assigns the signals received at the input of the PM Aux bus to the corresponding Wavetable oscillator.
2. **Aux Modulation Amount:** Adjusts the amount of phase modulation applied from the PM Aux bus to the Wavetable oscillators.
3. **PM Aux Bus:** This bus features a single input that sends signals to the phase modulation function of the Wavetable oscillators. It can be connected to the generators and processors in the Polyphonic Area.

Feedback loop

The feedback loop in the Polyphonic Area of the Routing page facilitates a connection from an output of a module to its input. Any number of modules can be chained in the feedback loop. This way you can add chaotic and non-linear behavior to the voice, which creates organic and distorted sounds. You can use feedback to enhance the sound or as a dramatic effect, with high feedback levels causing sonic mayhem. The feedback loop is also useful for physical modeling sounds, especially when combined with the Comb filter.

The feedback loop can be freely connected in the Polyphonic Area of the Routing page by using the two **FB** modules:

1. **FB (feedback) Loop Output:** This bus features a single output that receives signals from the feedback loop input. It can be connected to the generators, processors, and buses in the Polyphonic Area.
2. **FB (feedback) Loop Input:** This bus features a single input that sends signals to the feedback loop output. It can be connected to the generators and processors in the Polyphonic Area.

In the example above, the output of the Asimov filter is connected to the **FB** input, and the **FB** output is connected to the input of the Asimov filter. This creates a feedback loop around the filter, making it sound distorted and behave in unexpected yet interesting ways.

Note that the feedback loop is polyphonic, meaning it is processed independently for every single voice you play. This way you can play chords and overlapping notes with your feedback sounds.

Feedback Level Control

The feedback amount is controlled from the Amp module. Use the **FB** control to adjust the feedback level and apply a high-pass filter to reduce bass overloading in the feedback loop.

1. **FB (feedback) Level:** Adjusts the level, or volume of the feedback loop. This way you can control the chaotic behavior and distortion produced by the feedback.
2. **High-pass Filter:** Enables a high-pass filter that cuts low-frequency content in the feedback loop. When activated, you can avoid overloading the feedback loop with excessive bass.

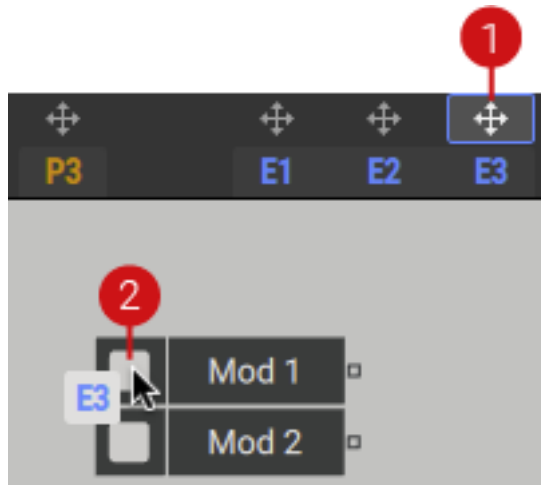

Modulation modules

The Modulation modules in the Polyphonic Area of the Routing page make it possible to use any of Massive X's modulation sources as generators in the signal path. For example, you can use the Switcher LFO in OSC mode as an additional oscillator, or the Exciter Envelope as an exciter for the Comb filter.

To assign a modulation source to a Modulation module in the Polyphonic Area:

1. Click the modulation source's arrow icon to select it.

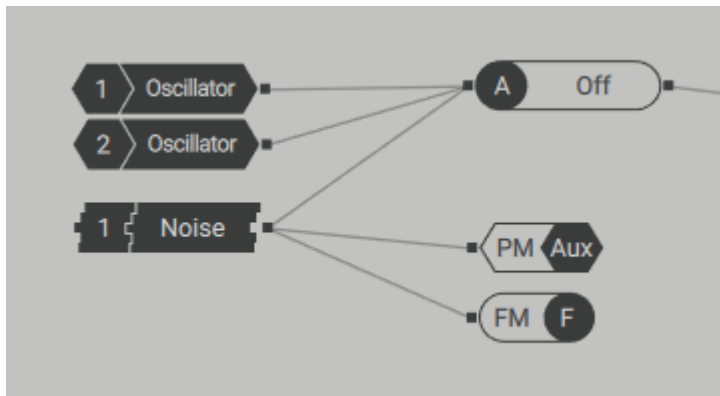

- Click on the Modulation module slot in the Polyphonic Area to assign it.

→ The signal produced by the modulation slot is now sent from the Modulation module's output and can be used anywhere in the signal path.

Using the Routing page

On the Routing page, you arrange and connect the individual building blocks, or modules, that make up the synthesizer. Connections between the modules' inputs and outputs are established using wires. Outputs can be connected to any number of inputs and vice versa. This way you can distribute signals to multiple destinations or mix multiple outputs into the same input:

Routing Workflows

To make a connection between modules:

- Click on an output to show all available inputs it can be connected to.
- Click on the input you want to connect the output to.

i Alternatively, you can click and drag from an output to an input to connect them.

To make an exclusive connection to an input, meaning that all existing connections to the input will be removed:

1. Click on an output to show all available inputs it can be connected to.
2. Right-click on the input you want to connect the output to exclusively.

To delete a wire:

► Double-click the wire you want to remove.

→ The wire is deleted.

To delete all connections from a module:

► Double-click the module that you want to remove all connections from.

→ All connections are deleted.

You can also bypass any number of modules directly on the Routing page. This provides a quick way of listening to the sonic impact that a generator or processor is having on the sound.

To bypass a module while keeping its connections intact:

► Right-click the module you want to bypass.

→ The module icon is dimmed and the module is deactivated.

11. Wavetable oscillators

 This feature is not available in Massive X Player.

Two Wavetable oscillators form the basis for sound generation in Massive X. These oscillators produce sound from digitally sampled, single-cycle waveforms arranged in a table known as a wavetable. Scanning through the different waveforms in the table gives you access to a wide range of tones and sound colors that can be used in various musical forms.

Wavetable synthesis operates on a two-dimensional axis. On the x-axis, playback of the individual waveforms occurs. This playback, or readout, is controlled by the internal phase of the oscillator, which follows the pitch of incoming MIDI notes. The y-axis represents the wavetable itself, and the different waveforms that are stacked one above the next. Scanning the different waveforms along the y-axis produces variations in harmonic content. By modifying the readout of the waveform, you can create intricate timbral variations in our sound.

The beauty and power of wavetable synthesis becomes most evident when modulation is introduced to scan the table of waveforms. This process can be triggered by an envelope or modulated by an LFO, as well as manually altered with a controller. The dynamic results of this morphing is a defining sonic character in this style of synthesis. Wavetable synthesis inherently facilitates complex combinations of different waveforms, and this sonic potential is further enhanced with the **Wavetable Modes**, which dramatically impact that readout of the wavetable. The modes also determine the available controls and menus, significantly altering the behavior of the oscillator.

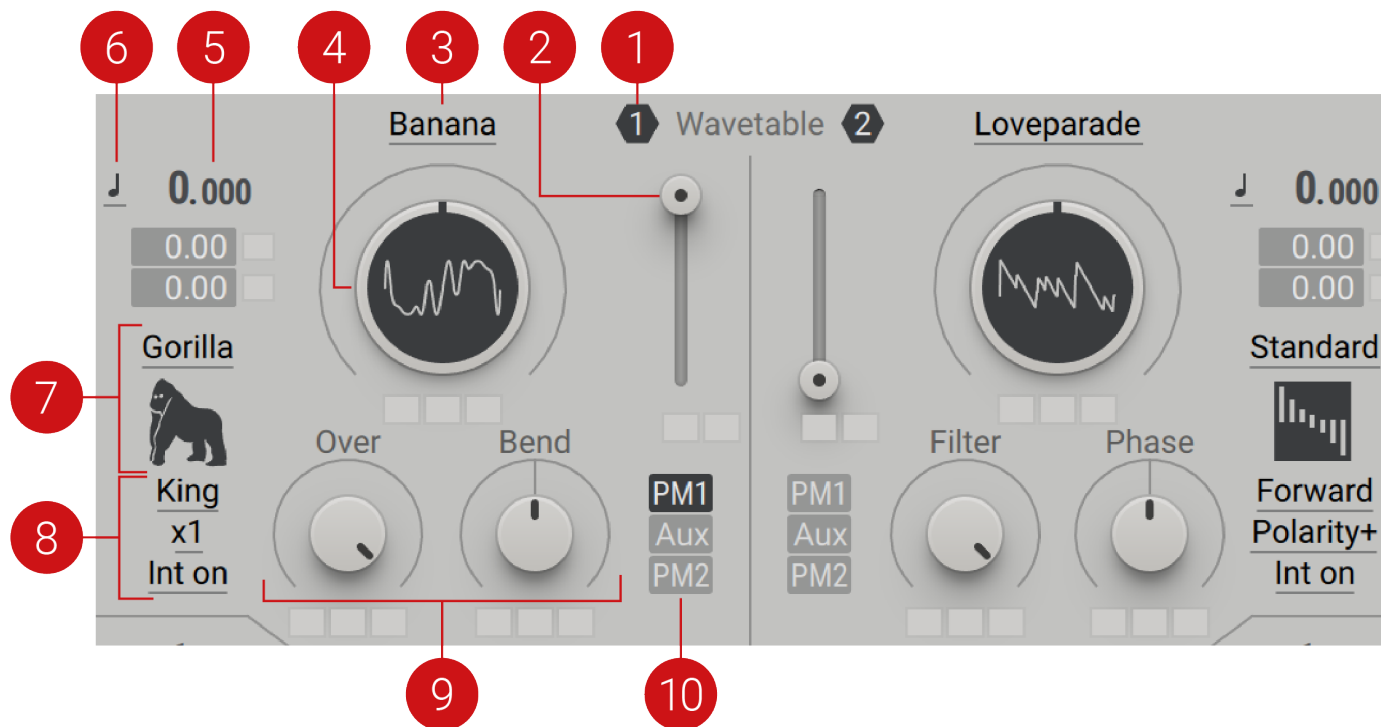

The Wavetable oscillators are defined by the selected wavetable and the wavetable mode. A diverse collection of wavetables has been crafted to cover a broad range of end uses, from more typical waveforms and PWM to FX and Harmonics. To start exploring the Wavetable oscillators, browse through the wavetables in the **Wavetable Menu** and experiment using these with the different **Wavetable Modes**.

Scanning through the waveforms included in the wavetable is done using the **Wavetable Position** control. Turning this knob scans through the waveforms included in the selected wavetable, the result of which is graphically displayed on the control. Intricate sweeping effects can be achieved by routing a modulation source to the **Wavetable Position knob**, producing a waveform that is constantly morphing and evolving.

The Wavetable oscillators can be used to replicate the timbre and articulation of acoustic instruments, or to shape new and abstract sounds. Complex drones, shimmery pads, abrasive leads and percussion can all be crafted using the oscillators as the core building block. When combined with the extensive modulation and routing options found in Massive X, alongside the PM/Aux bus, noise sources, effects, and Modulators, the potential is unbounded.

Wavetable oscillators overview

This section provides an overview of the Wavetable oscillators. Controls for Wavetable oscillator 1 are numbered below, and these controls are mirrored for Wavetable oscillator 2.

1. **Oscillator On/Off:** Switches the Wavetable oscillator on or off. The icon can also be found on the Wavetable oscillator module on the Routing page.
2. **Level:** Adjusts the output volume of the Wavetable oscillator.
3. **Wavetable Menu:** Opens a menu with available wavetables. The categories are presented on the left and the individual wavetables on the right. Hover over the Wavetable menu to expose arrows that allow you to browse up and down through the wavetables, without opening the menu. For more information on the wavetable categories, refer to [Wavetables menu](#).
4. **Wavetable Position:** Scans through the waveforms included in the selected wavetable. The individual waveforms represented in each table range from 2-128. Changes in the waveform are visually represented.
5. **Pitch:** Adjusts the tuning of the oscillator in semitones and cents. The **Pitch** can be modulated to produce vibrato and arpeggio effects by assigning a modulation source to either of the two modulation slots below.
6. **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determines the response of the oscillator in relation to incoming MIDI pitch.
 - **Keytrack** mode, locks the pitch to the main MIDI pitch.
 - **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic.
 - **Fix** mode sets the fixed tuning of the oscillator, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).
7. **Wavetable Modes:** Selects one of ten operating modes (Standard, Bend, Mirror, Hardsync, Wrap, Formant, ART, Gorilla, Random, Jitter), which determine the readout of the wavetables. For more information, refer to [Wavetable modes](#).
8. **Wavetable Mode settings:** Menus and switches that vary, depending on the mode selected. Each mode has a specific set of menus and switches that directly relate to its operation. For more information on the settings relating to each specific mode, refer to [Wavetable modes](#).

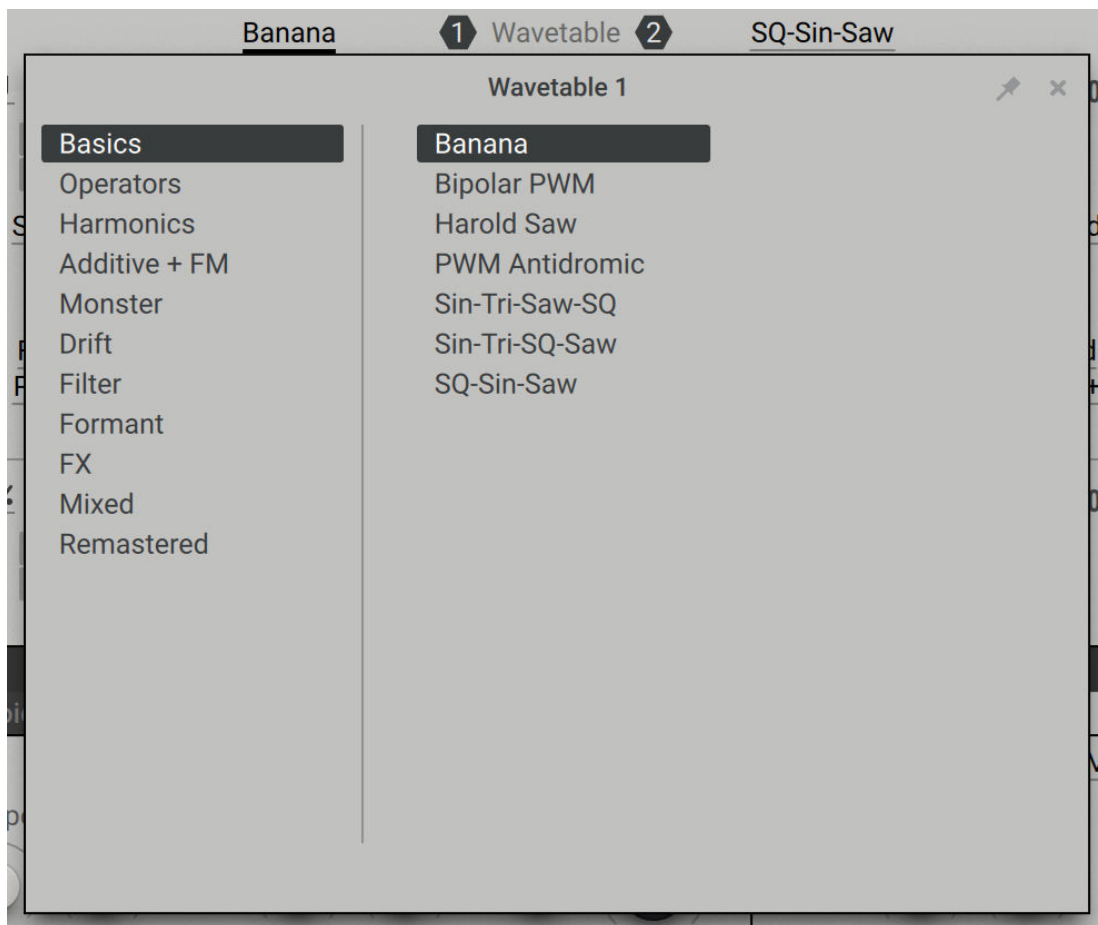

9. **Wavetable Mode controls:** Two control knobs that vary, depending on the selected Wavetable mode. Each mode has two knobs controls that directly relate to its operation. For more information on the controls relating to each mode, refer to [Wavetable modes](#).
10. **PM Aux Assignment:** When activated, the Phase Modulation oscillators and/or Aux input are assigned to the corresponding Wavetable oscillator. For more information on the PM/Aux bus, refer to [Phase modulation](#).

Wavetables menu

The wavetables in Massive X are grouped in to 11 categories (Basics, Operators, Harmonics, Additive + FM, Monster, Drift, Filter, Formant, FX, Mixed, Remastered) to help streamline your search, and provide you with an idea of proposed use-cases.

The wavetables are not strictly separated, and they can serve as the starting point for various kinds of sound design. However, the sonic content of some wavetables makes them more suitable in certain use cases than in others. For example, some wavetables are best suited for sounds based on subtractive synthesis, while others are specifically designed to be used for phase modulation. In some cases, the wavetables are not particularly exciting on their own, but work well in combination with other wavetables or specific wavetable modes. Experimenting with all controls is the best way to really understanding how the wavetable relates to the respective wavetable mode. For more information, refer to [Wavetable modes](#).

The Wavetable menu contains the following categories:

Basics

These wavetables do not have a distinct character, and serve as the basis for subtractive synthesis. The most basic table, **SQ-SIN-SAW**, is a good starting point for any type of synthesis. Basics also consists of some classic analog waveforms, including PWM (pulse width modulation). The **Banana** wavetable is especially designed for **Gorilla** mode, and produces its best results with modulation applied to the mode's **Over** and **Bend** controls. Wavetables found in the Basics category are well suited for classic analog synth sounds.

Operators

Operator wavetables are specifically made to be used for phase modulation, but they can also add body to a layered sound. **WM** (width modulation) is provided in wavetables that contain only few harmonics, allowing for a more dynamic and animated sound.

Harmonics

These wavetables feature a specific effect that emphasizes the harmonic series when scanning through the wavetable. They combine well with subtle filtering or EQ, and produce interesting results when applying modulation to the wavetable position.

Additive + FM

Wavetables in this category feature sounds typically associated with additive or FM synthesis. They are ideal for producing cold, shimmery, metallic, or glassy sounds.

Monster

As the name suggests, Monster wavetables have a particularly brutal tone and a strong character. They combine well with EQ, unisono and distortion. With additional phase modulation, or when used with modes like **Bend** or **Mirror**, even more aggressive timbres can be achieved. Applying modulation to the wavetable position with a sawtooth or triangle LFO creates the wobble sounds synonymous with EDM or dubstep. To tame these sounds, you can use clean filters like **SV Parallel** or **SV Serial**. The included wavetables named Gorilla can produce a similar effect as the Gorilla mode when scanning through the wavetable. All content in this category is usually played in the low to very low register.

Drift

These wavetables provide hard transients that work well with subtractive filtering, from standard and more complex **PWM** wavetables, to newly invented tables with the **Drift** feature. The tables create the illusion of multiple, slightly detuned oscillators beating against each other, allowing you to achieve a drifting effect with only one oscillator. To use this feature, apply a slowly moving triangle LFO to the wavetable position and alter the **Rate** of the LFO to produce the illusion of oscillator drift.

Filter

Wavetables that mimic filter sounds, including BP (band-pass) and LP (low-pass) options, are featured in this category. They combine well with EQ, unisono and distortion. Scanning through the wavetable emulates the effect of adjusting a filter's cutoff frequency at high resonance. This can produce similar sounding results to the wavetables in the **Harmonics** category. Due to the similarity of the effect, it is best to avoid combined these wavetables with resonant filters. Rather, they can effectively replace a resonant filter in the sound, while adding capabilities beyond normal filters.

Formant

These wavetables mimic characteristics of the human voice and can be used for creating vowel sounds. They work particularly well in **Formant Capture** mode. The vowel sounds become especially distinguished when modulation is applied to the **Wavetable Position**. Each wavetable has a different sweet spot that can be brought to life with the right modulation. Experiment with the modulation rate to emphasize human-like articulations and achieve nuanced vocalisms. Some of these wavetables are based on voice recordings, which were then transformed into wavetables.

FX

FX wavetables produce complex sound colors. They are suitable for sound effects rather than standard oscillator sounds, and can be used to add shimmer and texture to layered sounds. When transposed down drastically and used without pitch tracking, they can serve as noise generators without distinct pitch. You can use them to emulate environmental resonances, or to create inharmonic bell sounds. These wavetables are most effective with strong modulation applied to the **Wavetable Position**.

Mixed

Mixed wavetables are made up of a variety of highly unrelated waveforms, with differing sonic palettes. As such, they do not morph smoothly like most typical wavetables, but can be used to create interesting stepping effects.

Remastered

These wavetables are legacy content from the original Massive, which have been remastered for Massive X.

Wavetable modes

The Wavetable oscillator operates in one of ten different modes (**Standard**, **Bend**, **Mirror**, **Hardsync**, **Wrap**, **Formant**, **ART**, **Gorilla**, **Random**, **Jitter**), which determines the readout of the wavetables and hence the behaviour of the Wavetable oscillator. The modes have a significant impact on sound and are essential to unlocking the full potential for sound design using Massive X. Every mode features two dedicated parameters for real time manipulation and additional settings to define the behaviour.

Standard mode

The default Wavetable mode is Standard. Similar to Spectrum mode in original Massive, the **Filter** control is used to reduce the higher frequency harmonics heard in the selected waveform. By scanning through the set of band-limited waveforms that are usually assigned to specific pitches, a low-pass filtering effect is achieved. The function is similar to a low-pass filter cutoff, although the algorithm behind it is different from a standard filter design. When this filter is applied to a square wave it gradually becomes a sine wave, i.e. only the fundamental of the sine wave remains.

Standard mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determine the readout of the wavetables.
2. **Phase Direction:** Switches between two settings (Forward, Backward) which determine how the waveform is read out.
3. **Polarity +/-:** Switches from positive to negative polarity, meaning the waveform is flipped.
4. **Internal Phase On/Off:** When **Int on** is selected, the engine uses the main phase. Selecting **Int off** fixes the oscillator frequency at 0 Hz, bypassing the main phase and turning the oscillator into a waveshaper. The shaper must be used in conjunction with the PM oscillators or the PM Aux bus. The level of the PM oscillator and/or Aux input determines the amount of waveshaping, and the **Wavetable Position** and **Filter** parameters control the shape function.
5. **Filter:** Reduces the high frequency harmonics of the selected waveform. The effect is similar to adjusting the cutoff frequency of a low-pass filter.
6. **Phase:** Adjusts the oscillator phase.

Presets like **Amber Chapel** demonstrate a classic organ sound. **Analogica** produces a classic analog saw sound.

Bend mode

In Bend mode, the readout curve of the wavetables can be shaped. You can raise and lower the readout speed depending on the position within the wavetable. Some parts of the waveform are compressed and other parts are expanded, as determined by the Bend, Strength and Direction parameter settings. Up-down mode can be used to create a hollow, square-like sound.

Bend mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.

2. **Bend Curve:** Selects one of three settings (Strong, Medium, Gentle) that change the bend curve. With a **Strong** setting, the bending curve is significantly altered. **Medium** produces a less strong curve. With a **Gentle** setting the bend curve is more subtle, operating like the +/- Bend mode in Massive.
3. **Direction:** Selects one of three settings (Neutral, Up-Down, For-Back) that determine how the waveform is read out. With a **Neutral** setting, no directional change is applied and the waveforms are unaltered when played. **Up-Down** inverts every second cycle of the waveform. Flipping every second cycle cuts out all even harmonics (2, 4, 6, 8 etc.), meaning you cannot produce these harmonics with this setting. **For-Back** (Forward-Backwards) reads out every second cycle of the waveform backward. If the waveform is perfectly symmetrical, this has the same affect as **Up-Down** mode.
4. **Filter:** Reduces the high frequency harmonics of the selected waveform. The effect is similar to adjusting the cutoff frequency of a low-pass filter.
5. **Bend:** Bends the phase by accelerating and decelerating the readout of the waveform.

Start with presets like **Alkaline State** or **Alpha Ape** for a basic introduction to this mode. The **Anaphylaxis** preset showcases Bend mode, in combination with wavetables from the Monster category, producing a hollowed out square. The **Andean Air** preset demonstrates how to produce a breathy, hollowed instrument sound using two **Operator** wavetables in Bend mode.

Mirror mode

Mirror mode reads the wavetable back and forth. It has no sub menus. Exceeding a certain **Ratio** will force the waveform to be folded, producing a hard sync-style sound.

Mirror mode contains the following parameters and controls:

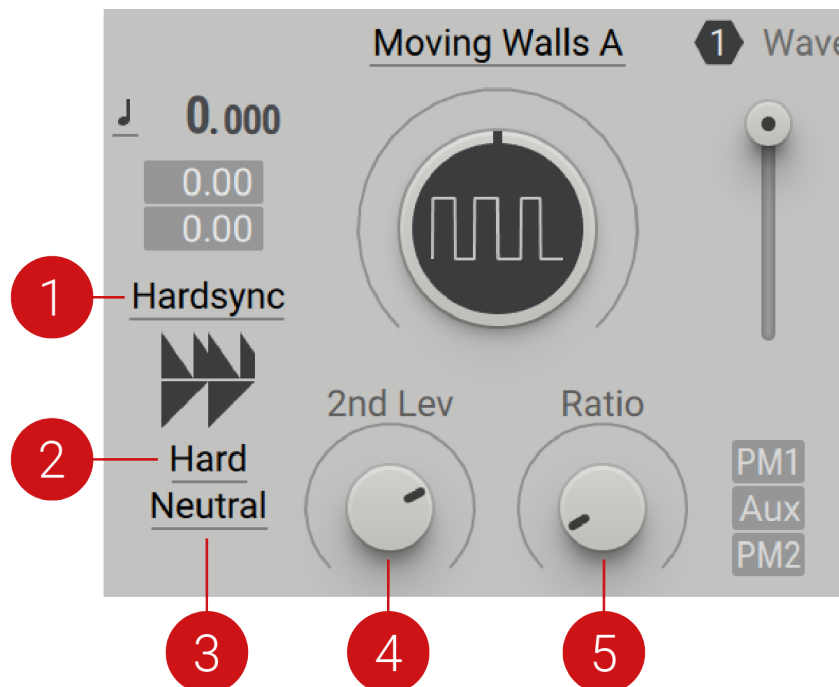

1. **Wavetable mode:** Selects from a menu of ten operating modes that determines the readout of the wavetables.

2. **Bend:** Bends the phase by accelerating and decelerating the readout of the waveform.
3. **Ratio:** Controls the depth ratio of the mirrored phase. You can successively change the range of mirroring, and even force it to folding, where the sonic results will enter hard-sync territory.

Hardsync mode

Hardsync mode offers the classic hard sync sound, as well as other variations of this effect. Unlike with traditional analog synthesizers, no second oscillator is required to reset and achieve the effect. This mode produces a completely different sound to a standard wavetable readout. You can use the other Wavetable oscillator to add body to the sound. Alternatively, you can use the Insert oscillator with a sawtooth or square waveform in Lock mode. With a high amount setting, the sound is likely to be sharp. Soft and Grain settings can be used to smooth the reset; options that are not possible with classic analog hard sync.

Hardsync mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.
2. **Window:** Selects one of three settings (Hard, Soft, Grain). **Hard** applies no smoothing window to the resetted waveform, resulting in the typical rolling sound of classic hard sync. **Soft** fades out the waveform before the reset occurs, producing a rounder and more even sound. This setting creates a smoother and softer sound, with a less exaggerated quality. **Grain** has an even softer effect, producing a very round waveform that fades in and out at the start of each sync. The resetting is completely smoothed out, resulting in a sound with less bite. With a round waveform, **Grain** is the same as the Formant mode found in Massive.
3. **Direction:** Selects one of three settings (Neutral, Up-Down, For-Back) that determines how the waveform is read out. With a **Neutral** setting, no directional change is applied and the waveforms are unaltered when played. **Up-Down** inverts every second cycle of the waveform. Flipping every second cycle cuts out all even harmonics (2, 4, 6, 8 etc.), meaning you cannot produce these harmonics with this setting. **For-Back** (Forward-Backwards) reads out every second cycle of the waveform backward. If the waveform is perfectly symmetrical, this has the same affect as **Up-Down** mode.

4. **2nd level knob:** Controls the amplitude of every second resetted repetition of the cycle. Turning the knob fully left will produce the sound at an octave lower.
5. **Ratio knob:** Sets the frequency ratio of the inaudible sync oscillator, which is used to reset the main oscillator.

Wrap mode

Wrap mode is close to Hardsync mode, the difference between the two becomes evident when modulation is applied. When modulated, Hardsync mode will create more pitch artefacts. Starting in the centre it can create a ramp, cutting when it reaches the boundaries of the waveform.

Wrap mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.
2. **Window:** Selects one of three sub-settings (Hard, Soft, Grain). The **Hard** setting applies a very subtle smoothing window to the end and start point of the fundamental cycle. Depending on the waveform, this results in the typical sound of classic hard sync. **Soft** applies a smoother window and **Grain** applies the smoothest window.
3. **Direction:** Selects one of three settings (Neutral, Up-Down, For-Back) that determines how the waveform is read out. With a **Neutral** setting, no directional change is applied and the waveforms are unaltered when played. **Up-Down** inverts every second cycle of the waveform. Flipping every second cycle cuts out all even harmonics (2, 4, 6, 8 etc.), meaning you cannot produce these harmonics with this setting. **For-Back** (Forward-Backwards) reads out every second cycle of the waveform backward. If the waveform is perfectly symmetrical, this has the same affect as **Up-Down** mode.
4. **Filter:** Reduces the high frequency harmonics of the selected waveform. The effect is similar to adjusting the cutoff frequency of a low-pass filter.
5. **Ratio:** Sets the frequency ratio of the inaudible sync oscillator, which is used to reset the main oscillator. It operates in a centered way, so that the cycle-multiplications take place from the center of the cycle, equally to the left and right.

Presets like **Ample Wob** highlights the hard-sync style effect, when Wrap mode is combined with a square waveform.

Formant Capture mode

Formant mode manipulates the waveform in such a way that the amplitude of the signal does not change over altering pitches. This provokes an unusual sonic experience, by creating the impression that the waveform remains static over different pitches. Essentially, the sound is initially corrected so that it works as a static formant, erasing the original 'Mickey Mouse' effect. A Formant control then offers the ability to reintroduce the Mickey Mouse effect, independent from pitch.

Each wavetable is imprinted with an extra metadata called Formant Center, which informs the engine where the original table was made. Formant mode uses only one specialised windowing algorithm, rather than two overlapping grains (as used in PSOLA Synthesis), for a clearer sound and lower CPU load.

This mode is most effective when a strong formant is present in the wavetable itself, hence it does not work so well with sine, sawtooth or square waveforms. Wavetables found in the **Formant** category are especially suited to Formant Capture Mode. These wavetables mimic characteristics of the human voice and can be used specifically for creating vowel sounds.

Formant Capture mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.
2. **Direction:** Selects one of three settings (Neutral, Up-Down, For-Back) that determine how the waveform is read out. With a **Neutral** setting, no directional change is applied and the waveforms are always played one after the other. **Up-Down** inverts every second fundamental cycle of the waveform. **For-Back** (Forward-Backwards) reads out every second fundamental cycle of the waveform backwards.

3. **2nd Level:** Controls the amplitude of the second repeat of the waveform. Turning the knob fully left will produce the sound an octave lower.
4. **Formant:** This knob reintroduces the formant, or the 'Mickey Mouse' effect.

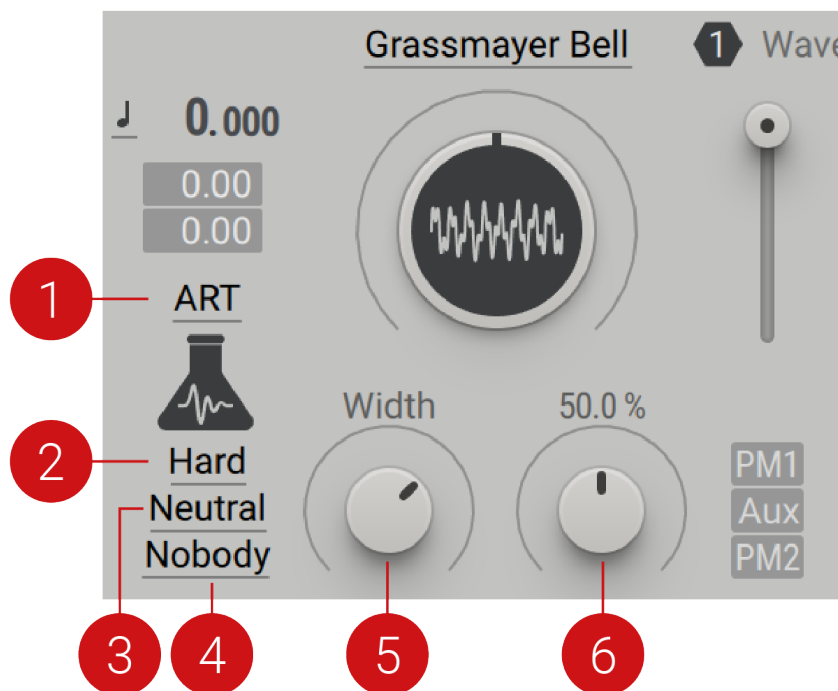

To get started, try the Talkative SQ waveform with the **2nd Level** control turned fully left. Combine this with an SVF Parallel or Groain filter and adjust the filter **Cutoff** and the **Wavetable Position** to find a vocal sound that speaks to you. Apply an LFO to each control and experiment with the modulation **Rate** and **Amount**. For a more subtle vocal effect, check out the **Android** preset that combines wavetables from the **Formant** and **Basic** categories.

ART mode

ART (Artificial Resonance Technology) mode utilises hard sync techniques and windowing to mimic a resonant filter. The basic idea for this mode was to create filters without filters. In contrast to standard analog modelling, the numerical approach of creating filters without filter, means that more unusual filtering options can be explored. ART mode provides you with some of the fundamental sound principles of a filter, closely replicating a high resonating bandpass filter sweep. It combines this with the possibilities of a traditional wavetable scanning oscillator to create new variations of filtering sound, also expanding into the artificial filter territories that a real filter cannot achieve. This mode relies on modulation for the most effective and interesting results. It is the only mode where the **FU-DB** sub-mode can be found.

For a basic introduction to ART mode, start with a sine waveform in the Wavetable oscillator and a high **Width** setting. Turn the **Pitch** control, aiming to produce some realistic filter sweeps. Switch to a square waveform and note how much more aggressive the sound instantly becomes.

ART mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determine the readout of the wavetables.

2. **Window** Selects from three strength settings (Hard, Bity, Soft) that influence the shape of the impulse envelope. **Hard** is the most aggressive setting, creating a sharp sound. **Soft** is smooth sounding and the least aggressive setting. **Bity** has a balanced character and is a good starting point. The differences in the three modes can best be heard with low **Pitch** settings.
3. **Direction**: Selects one of three settings (Neutral, Up-Down, For-back) that determine how the waveform is read out. With a **Neutral** setting, no directional change is applied and the waveforms are always played one after the other. **Up-Down** inverts every second cycle of the waveform. By flipping every second cycle, all even harmonics (2, 4, 6, 8 etc.) are cut out, meaning you cannot produce harmonics with this setting. **For-Back** (Forward-Backwards) reads out every second cycle of the waveform backwards. This setting will sound the same if the waveform is perfectly symmetrical. **FU-DB** (Forwards Upwards - Downwards Backwards) combines Up-down and For-back.
4. **Body**: Selects one of two settings (Body, Nobody), which determine if the response of an artificial body is applied to the sound. When **Body** is active, this response adds bass to the sound. When **Nobody** is selected, you have the excitation response of an artificial filter.
5. **Width knob**: Narrows or widens the envelope, mimicking the resonance impulse. The effect is similar to adjusting the resonance amount of a normal filter.
6. **Pitch knob**: Adjusts the frequency of the artificial resonance, similar to the cutoff frequency on an analog filter.

The signature filtering effect that is described above, is best demonstrated in presets like **Alpine Digital**, **BAMX2** and **Golden Child**.

Gorilla mode

Gorilla mode is for the vulgar and obscene! It is an aggressive sounding mode that produces uniquely exaggerated results. Input waveforms with minimal spectral complexity are most effective, as this mode already creates a high number of harmonics in the frequency spectrum.

Gorilla mode contains the following parameters and controls:

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.
2. **Kings:** Selects one of three settings (King, Kong, Kang), which determines the type of bend applied to the phase to achieve sonic variations. **King** is the cleanest sounding option, providing the classic screaming sound. **Kang** provides medium bending for a dirtier sound. **Kong** has maximal bending for the dirtiest sound.
3. **Ratio:** Selects one of six ratios (x1, x2, x3, x4, x5, x6) that changes the frequency ratio of a second internal oscillator phase. This control has a strong impact on the overall 'hybrid color' of the sound. A ratio of x2 is recommended to achieve the prime Gorilla sound.
4. **Internal Phase On/Off:** When **Int on** is selected, the engine uses the main phase. Selecting **Int off** fixes the oscillator frequency at 0 Hz, bypassing the main phase and turning the oscillator into a waveshaper. In this instance, the main phase is replaced by the phases provided by the modulation oscillators, which can be used to make the sound inharmonic. The shaper must be used in conjunction with the PM oscillators or the PM Aux bus. The level of the PM oscillator and/or Aux input determines the amount of waveshaping, and the wavetable position and filter parameters control the shape function. Using the main phase should be the standard option for this mode.
5. **Over knob:** Controls the strength of the mode. Turn the knob right to introduce more of the 'Gorilla' effect.
6. **Bend knob:** Creates the formants together with the **Over** control. For the best effect, the **Over** and **Bend** controls should be modulated together.

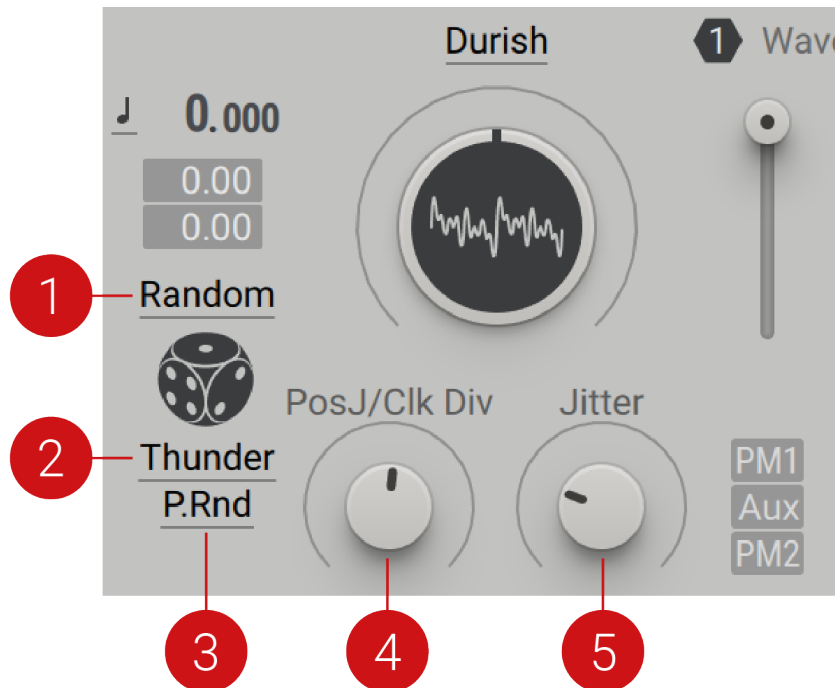

To get started, try the 'Banana' waveform with a **x2** ratio setting, and a modulation source applied to both the **Over** and **Bend** controls.

Random mode

A special mode that is dedicated to creating unusual noise sounds. This mode uses two internal randomizers which are applied to the signal in several ways. Random mode is even more extreme than the effect created in Jitter mode.

Random mode contains the following parameters and controls:

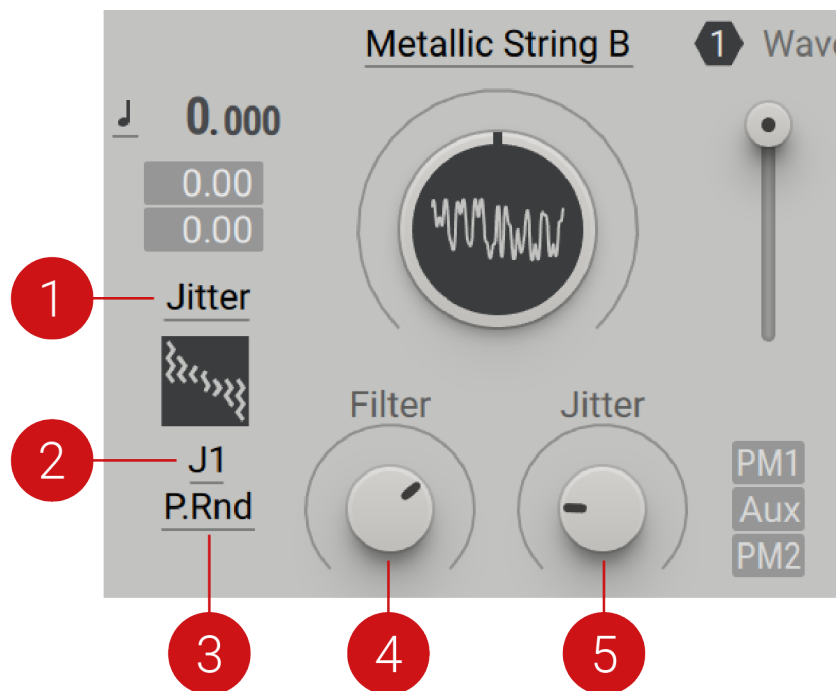

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.
2. **Mode:** Selects one of three modes (Fluid, Thunder, Divide) that determine the behaviour of the **Pos J/Clk Div** and **Jitter** controls. The sonic outcome is highly dependant on the selected mode. In **Fluid** mode, the **PosJ/Clk Div** randomizes the wavetable position reader and the **Jitter** knob changes the amount of randomization applied to the oscillator's fundamental frequency. In **Thunder** mode, the **PosJ/Clk Div** randomizes the position and also downclocks the position of the randomizer. The **Jitter** knob randomizes frequency independently to the Position Jitter control. In **Divide** mode, the **PosJ/Clk Div** downclocks the Jitter's frequency randomizer. It does not add or subtract a random deviation on each cycle, but for example, only every 10th cycle. The **Jitter** knob changes the amount of randomization applied to the oscillator's fundamental frequency.
3. **P.Rnd (Pitch Random):** Selects between two modes (Pitch Random, Pitch Switch). When **P.Rnd** is selected, randomization is applied every cycle, depending on the Jitter rate. The pitch setting determines if it will play faster or slower. **P. Switch** makes static, quantized deviations, rather than random speed deviations.
4. **Position Jitter/Clock Divide knob:** Depending on the selected Mode, this knob operates in different ways, relating to the wavetable position readout and the down clocking of the internal randomizers.
5. **Jitter knob:** Changes the amount of randomization applied to the oscillator's fundamental frequency. Frequency randomization is only happening synchronous to the start of a wave cycle. The effect ranges from subtle jitter to total sound destruction.

Jitter mode

Jitter mode introduces random deviations at the end of each cycle, making the signal read out faster or softer. This mode is most effective with a harmonically sparse waveform, like those found in the **Basics** category. Jitter mode adds a glittery quality to these simple waveforms. The effect can become harsher and more intense as the Jitter strength is increased.

Jitter mode contains the following parameters and controls:

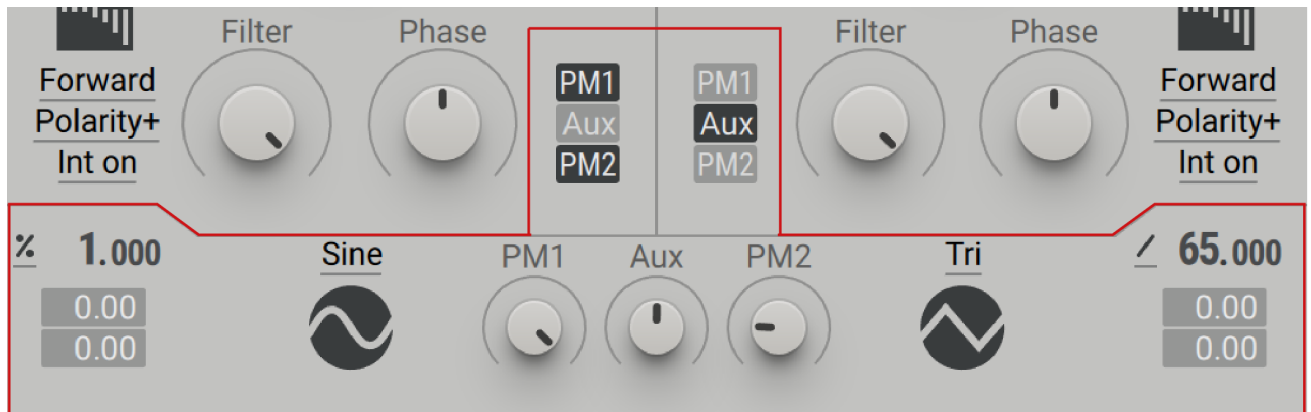

1. **Wavetable modes:** Selects from a menu of ten operating modes that determines the readout of the wavetables.
2. **Jitter Rate:** How often the signal is flipped, every time a cycle is done. This allows you to spread out the randomization so that it does not sound too busy. **J1:** Every cycle, randomization is applied **J2:** Every 32 cycle **J3:** Every 128 cycle
3. **P.Rnd (Pitch Random):** Selects between two modes (Pitch Random, Pitch Switch). When **P.Rnd** is selected, randomization is applied every cycle, depending on the Jitter rate. The pitch setting determines if it will play faster or slower. **P. Switch** makes static, quantized deviations, rather than random speed deviations.
4. **Filter knob:** Reduces the high frequency harmonics of the selected waveform. The effect is similar to adjusting the cutoff frequency of a low-pass filter.
5. **Jitter knob:** Adjusts the strength of the effect from soft to strong. You can create noise by combining high pitch with a high Jitter setting.

To get started, try the preset **Aerial List** to hear a **Drift** wavetable producing a classic 80s television show sound. The **Ancient Strings** preset showcases a more subtle shimmer effect, when paired with a **Drift** wavetable in Standard mode.

Phase modulation

Phase modulation is a synthesis technique used in classic FM (frequency modulation) synthesizers. One oscillator works as the carrier, while a second oscillator is used to modulate the phase of the signal. The final waveform is the resulting summation of the two oscillators, and the harmonic overtones and undertones that are created as the waves rise and fall in combination. Phase modulation creates rich harmonic sounds that can be used for a range of sonic tasks, including plucked basses, digital pianos, bells, and abstract soundscapes. In Massive X, phase modulation is incorporated into the synth engine in a variety of ways.

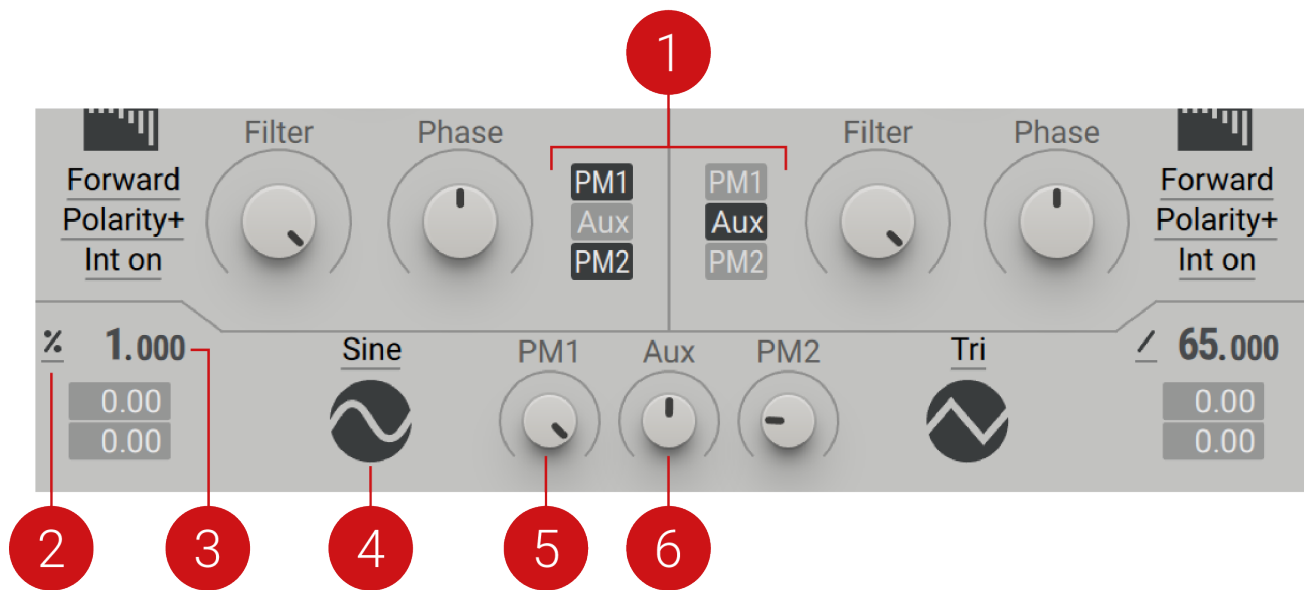

Massive X contains two PM oscillators and an additional Aux input. Each of these sources can be assigned to one or both of the Wavetable oscillators. The PM oscillators offer six variations on sine and triangle waveforms, which are used solely to modulate the phase of the Wavetable oscillators. From pure sine and triangle waves to variations of each, these waveforms have minimal harmonic spectral content that makes them ideal as a modulator signal.

Three Pitch modes produce distinct results, each suited to a range of different end uses. In Ratio mode, the pitch of the PM oscillator can be used to raise or lower the pitch in octaves. Key Track mode allows you to set the pitch in relation to the main pitch, and is useful for producing thick bass sounds, and metallic highs. Fix mode is particularly effective for percussive sounds that require no pitch.

The PM Aux bus opens up the ability for phase modulation in Massive X. Via the Routing page, any source in the signal path can be used to apply phase modulation to the Wavetable oscillators. This allows for phase modulation feedback or cross-modulation from other sound sources in Massive X. For more information on setting up the PM Aux bus in the Routing section, refer to [PM Aux bus](#).

Phase Modulation oscillators

This section provides an overview of the PM oscillators. Controls for PM1 are numbered below, and these controls are mirrored for PM2:

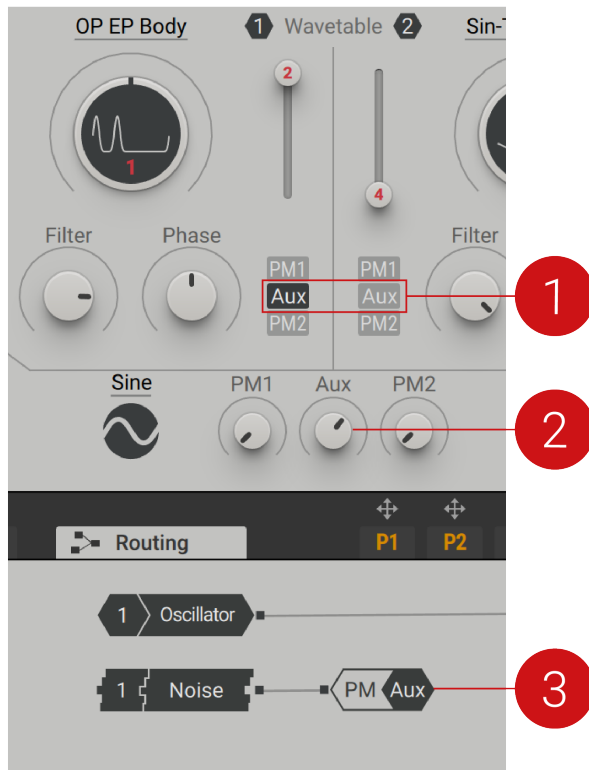

1. **PM Aux Assignment:** Assigns the PM oscillators and/or Aux input to the corresponding Wavetable oscillator. Click the button to activate the assignment.
2. **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determines the response of the PM1 oscillator in relation to incoming MIDI pitch.
 - In **Keytrack** mode, the pitch is locked to the main MIDI pitch.
 - **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic.
 - **Fix** mode sets the fixed tuning of the oscillator, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).
3. **Pitch:** Adjusts the tuning of the PM1 oscillator in semitones and cents. The **Pitch** can be modulated by assigning a modulation source to either of the two modulation slots, and setting the amount of modulation below.
4. **PM1 menu:** Selects from six waveforms (Sine, Tri, TriB1, TriB2, TriB3, SinN) that sets the waveform type for the PM oscillator. The selected wave cycle is visually illustrated below the menu.
5. **PM1 amount:** Adjusts the amount of phase modulation applied from the PM oscillator to the Wavetable oscillators. This control can be modulated by assigning a modulation source to either of the two modulation slots below the knob. The modulation slots are displayed a source is selected.
6. **Aux amount:** Adjusts the amount of phase modulation applied from the PM Aux bus to the Wavetable oscillators. The PM Aux bus makes the phase modulation inputs of the Wavetable oscillators accessible from the Routing page. Any source can be routed to the PM Aux bus, and used to apply phase modulation to the oscillators. For more information, refer to [PM Aux bus](#).

PM Aux bus

The Auxiliary bus offers an additional input for phase modulation, accessed from the Routing page. This input source can be assigned to one or both oscillators. The Aux bus allows phase modulation or cross-modulation to be applied to the Wavetable oscillators from various sources within Massive X. Any sound source can be routed to the phase modulation inputs of the oscillators.

The PM Aux bus has a dedicated module in the Routing page and additional controls on the panel of the Wavetable oscillators:

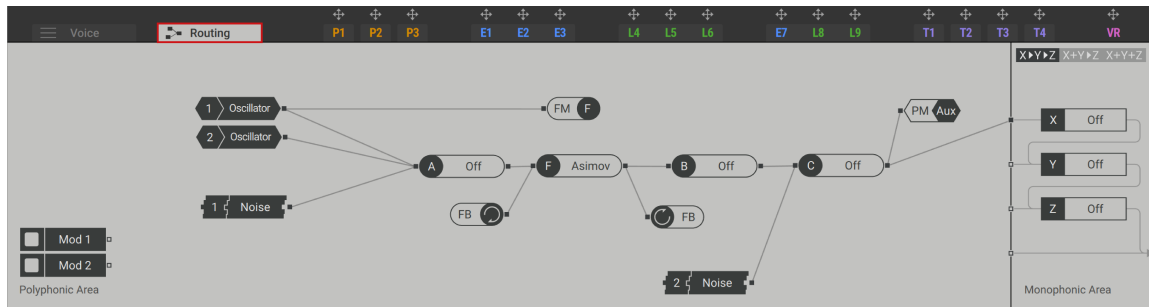

1. **Aux Assignment:** When activated, the signal received at the input of the **PM Aux bus** (in the Polyphonic Area of the Routing page) is assigned to the corresponding Wavetable oscillator.
2. **Aux Modulation Amount:** Adjusts the amount of phase modulation applied from the **PM Aux bus** to the Wavetable oscillators.
3. **PM Aux Bus:** This module features a single input that sends signals to the phase modulation function of the Wavetable oscillators. It can be connected to the generators and processors in the Routing page.

Routing

The flexibility in routing enables you to use the PM Aux bus to experiment with noise, feedback, and effects to achieve cross-feeding of operators or phase feedback chains within itself. For more information, refer to [Routing](#).

To assign an input source to the Aux bus:

1. Select preset **Init - Massive X**, found in the Quickstart category.
 2. Open the Routing page. This preset offers pre-configured routing based on subtractive synthesis with Wavetable oscillators. By default, this preset has the output of the PM Aux module patched to the input of the Insert Effect C, shown in the screenshot below.
 3. Assign a source module to the Aux bus by clicking on the output of the source module, then clicking on the input of the PM Aux module.
 4. In the PM Aux bus assignment section, enable **Aux** for Wavetable oscillator 1.
- The source module is assigned to the PM Aux bus. Play notes and adjust the **Aux Amount** control to hear the effect of the phase modulation of the Wavetable oscillator.

To start off, try assigning an Effects or Noise module to the PM Aux input. These are good starting points to explore other sonic possibilities for phase modulation using the PM Aux module. For examples of how Noise and Effects can be used in the PM Aux bus, check out the presets **Noise Sub**, **Crown Alloy**, and **Woozie**, found in the Mallet Instruments category.

12. Noise

 This feature is not available in Massive X Player.

Noise in synthesis can be used for a number of practical and creative end uses. As an audio source, noise can be mixed with other sound generators to produce harmonically rich waveforms. It can add depth and color to an otherwise lack-lustre waveform, and in sound design, it is essential for recreating the sonic character and texture of real-world elements like water, wind, fire and all soundscapes in between. Noise is also an ideal source for producing percussive sounds, like cymbals, snares and hi-hats. As a control source, it can be used to generate random voltages that can be utilised in a variety of ways, most commonly in sample-and-hold devices.

The Noise section in Massive X contains two noise sources, each offering the ability to add textures and atmospheric content to your sound. Beyond the typical white and pink noise offered on most synthesizers, the noisetables in Massive X provide huge potential for compelling and dramatic sound design. Collections of individual noise samples are grouped into seven categories. Alongside the standard noisetables, recordings from machines, animals, and environments are also provided, as well as transient samples that are particularly suited for percussive sounds.

Each noise source can be routed separately within the routing section, providing further opportunities in sound design. For more information, refer to [Generators and processors](#). The phase position and playback mode of the noise sources is defined in the Voicing page. By default, noisetables playback as a loop, with a *Phase* control to adjust the phase position of the sample playback. When One Shot mode is selected, the sample plays through once only. The *Phase* knob changes to *Start*, which determines the start position of the sample playback. This setting is accessed in the Voicing page, refer to [Noise Engine](#) for more information.

Noise overview

This section provides an overview of the Noise section. Controls for Noise 1 are numbered below and are mirrored for Noise 2:

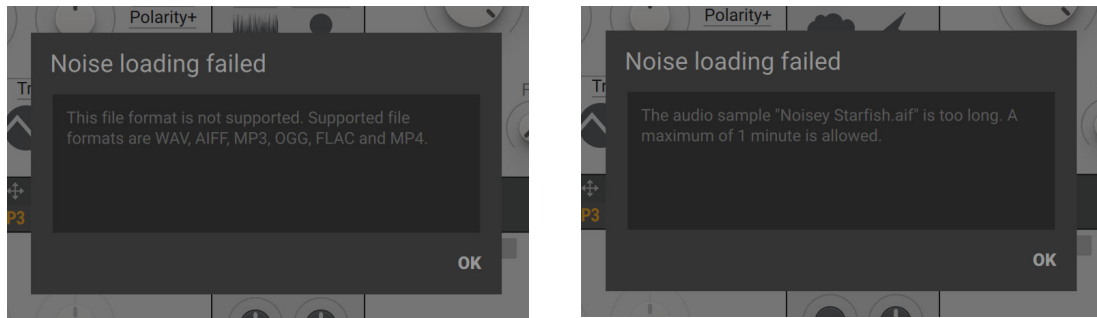

1. **Noise on/off:** Switches the Noise module on or off.
2. **Noise Level:** Adjusts the output volume of the noise source. Move the slider up to increase the level.
3. **Noisetable menu:** Opens a menu with available noises. Seven categories (Static, Friction, Processed, Environment, Machines, Beings, Transients) are presented on the left, and the noisetables of the selected category are displayed on the right. User noisetables are also added and loaded here.
4. **Browse** (^ v icons): Browses through the noisetables, without having to open the Noisetable menu. Hover over the noise category icons to reveal the browse arrows.
5. **Pitch mode:** Selects one of two modes (Key Track, Fix) that determines the response of the noise source in relation to incoming MIDI pitch. In **Key Track** mode, the pitch is locked to the main MIDI pitch. **Fix** mode sets the fixed tuning of the noise source, disregarding the incoming MIDI pitch. At centre position (0), the default is set to C3.
6. **Pitch:** Determines the base pitch/frequency for the noise source. At center position, the noisetable plays back at its original pitch. Lower the **Pitch** to slow down the playback, or increase it to speed up playback.

User noisetables

In addition to the factory noisetables provided, you can also import and load your own custom noise samples into Massive X. Accessing custom noisetables has significant implications for sound design, enabling you to add your own distinct color and character to the the Massive X synth engine. User noisetables that are saved with a preset are embedded into the preset file. For more information on importing samples, refer to [Importing user noisetables](#).

File Format and Size

The supported file formats for user noisetables are WAV, FLAC, AIFF, MP3, OGG and MP4. Samples must be at least 10ms long and a maximum of 1 minute. If a sample is too long or too short, a dialog will appear, alerting you to the recognised problem.

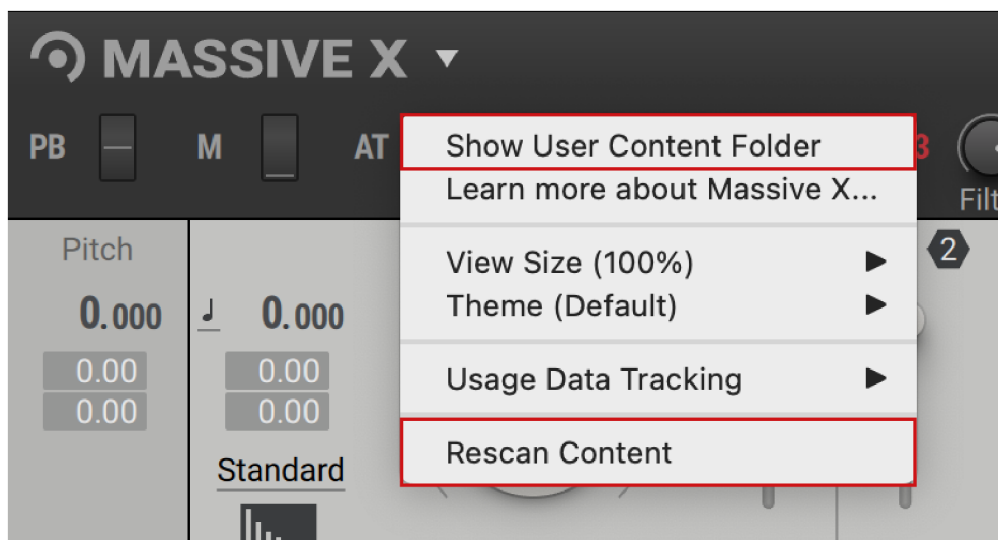

Warning Dialogs for non-supported samples.

Sample Rate

All sample rates are supported for user noisetables. A sample rate of 88200Hz is supported in Massive X, and any user noise sample with a sampling rate higher or lower than 88200Hz will be automatically converted upon import. All stereo samples will be converted to mono. Monophonic samples will not be converted.

Managing user noisetables

There are two options provided in the Settings menu to help you manage your user noisetables: **Show User Content Folder** and **Rescan Content**.

Viewing user noisetables

Show User Content Folder gives you quick access to all noise samples that have been added to the User Noisetables folder. It will not show added folders.

To view or edit the names of your User noisetable files:

1. Open the Settings menu, via the drop-down menu next to the Massive X logo.
2. In the Settings menu, select **Show User Content Folder**.
3. Use the dialog that opens to view, sort or rename your User noisetable files.
4. When you have finished, rescan your noisetables to reflect any changes made in the Massive X Browser.

Rescanning user noisetables

When a noisetable has been added, deleted or renamed, it is necessary to perform a rescan. Only by rescanning your User Noisetables folder can Massive X actively reflect these changes in the Browser.

To rescan your Noisetables folder:

1. Click the drop-down menu next to the Massive X logo, on the left-hand side of the Header.
2. In the Settings menu, click **Rescan Content**.

→ The Browser is updated to reflect the files in the User Noisetables folder.

The User Noisetables folder is located in the folder path: *Documents/Native Instruments/User Content/Massive X/Noisetables*.

Importing user noisetables

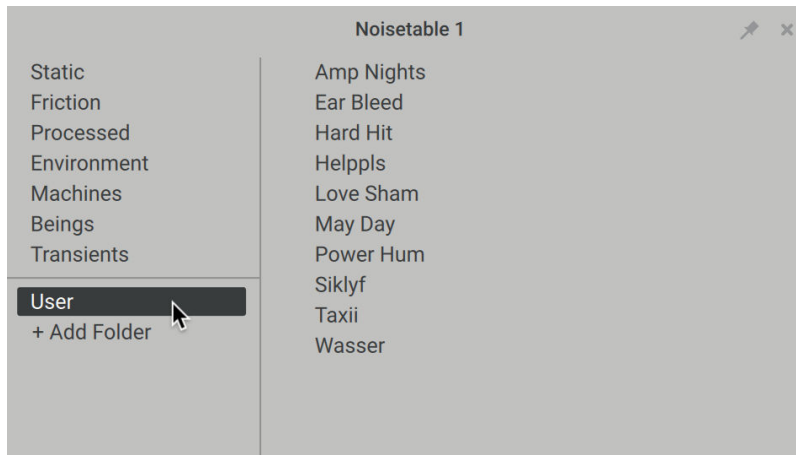

There are three ways to load your custom noise samples in Massive X. Samples can be imported in custom folders via the Noisetable menu, added to the user Noisetables folder on your computer, or loaded individually with drag and drop.

Importing to the User folder

To import samples into the User category of the Noisetable menu:

1. Open the Settings menu in the Header and select **Show User Content Folder**. This will direct you to the User Noisetables folder.
2. Open the *Noisetables* folder and manually add your noise samples.
3. Select **Rescan Content** from the Settings menu.

→ Your noise samples will be available in the User category in the Noisetable menu.

Importing noise samples into the User category.

New content must be scanned, otherwise it will not appear in the Noisetable menu. The *Noisetables* subfolder is the only folder in the User Content folder that will be scanned for noisetables.

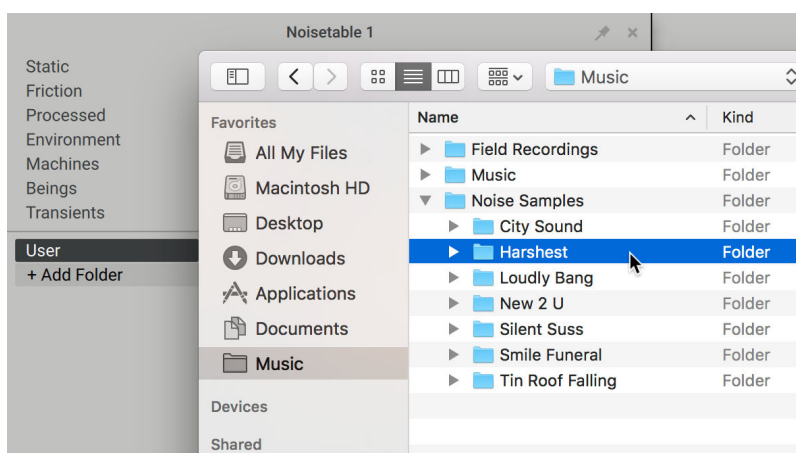

Adding a custom folder

While samples can be manually added to the User Noisetables folder, subfolders will not be scanned. Folders must be created from within the Noisetable menu, using **+Add Folder**. This method means that the folder name will be displayed in the Noisetable menu, enabling you to create your own user categories.

To import a folder of samples:

1. Open the Noisetable menu and select **+Add Folder**.
2. Locate the folder of samples on your computer and click **Open**.

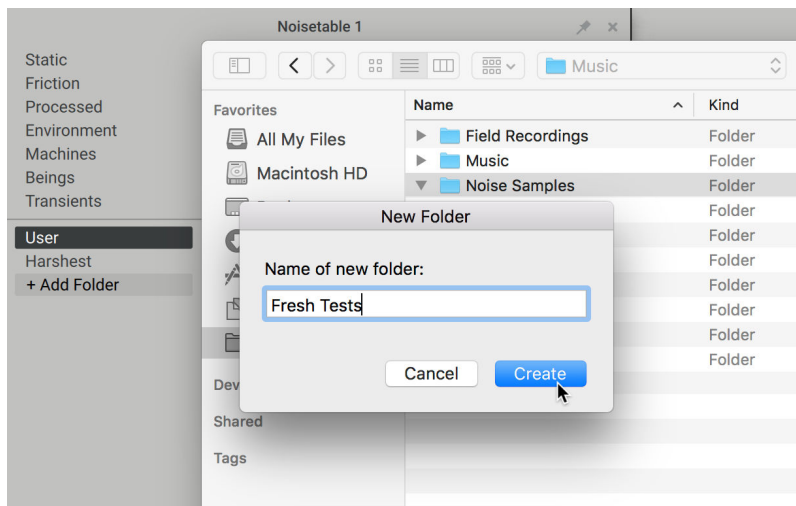

→ The selected folder of samples are now available in the Noisetable menu. A reference is added to your selected folder.

Adding a folder of custom samples to the Noisetable menu

1. Alternatively, if you choose to create a **New Folder**, select the location and enter the name of your new folder.

2. Select **Create**, then select **Open** and a dialog box will appear informing you that the **Added folder does not contain samples**.
 3. Copy and paste your noise samples into the new folder.
 4. Select **Rescan Content** from the Settings menu.
- The selected folder of samples is displayed in the Noisetable menu. A reference is added to the folder.

Creating and adding a new folder of samples in the Noisetable menu

Loading with drag and drop

You can also drag and drop a single noise sample onto the Noise players and the sample will immediately load in Massive X. A sample loaded via this method is not be added to the User Noisetables folder, but instead appears in a **Temporary Content** folder in the Noisetable menu. This is useful if you are wanting to test a noise sample in Massive X, without having to do a full import or rescan.

To import a sample using drag and drop:

1. Locate the noise sample on your computer.
 2. Drag and drop the sample onto a Noise player.
- The sample loads in the Noise player. The category icon changes to the User icon.

Dragging a sample into the Noise player

13. Filter

The Filter is a key element in Massive X's voice architecture. It offers nine different types of filters that cover a wide range of different applications. It can be used to balance and correct the tone of a sound, to sculpt complex timbres from raw waveforms, and to transform sounds beyond recognition.

i This feature is not available in Massive X Player.

Additionally, a number of filter types can be set into oscillation and become sound generators on their own. In some instances, this can be achieved by increasing the resonance for self-oscillation, in other instances the filter can be excited using the special Exciter envelope or noise signals for physical modeling sounds. Selecting where to place the Filter in the signal chain is done via the Routing page. For more information, see [Generators and processors](#).

The Filter section contains the following key elements:

1. **Bypass switch:** Switches the Filter's bypass function on or off. The icon can also be found on the Filter module on the Routing page.
2. **Filter menu:** Selects the filter type.
3. **Parameter controls:** This area hosts a range of buttons and knobs that control different parameters of the selected filter type. Each filter type has a different selection of controls that relate to its behavior and operation.

Asimov

This low-pass filter is based on the paradigm of the filter found in a classic bass synthesizer from the 80s, despite not being a direct clone. Its defining characteristic is the lack of self-oscillation, providing a huge sweet-spot for resonant filter sounds. Additionally, it adds high-pass filtering in the feedback path for a controlled bass response. The filter has a squelchy sound that makes it suitable for acid bass lines and works well with distortion.

Asimov contains the following parameters and controls:

- **Filter mode:** Selects one of three modes (LP1, LP2, LP4) that determine the steepness of the low-pass filter. **LP1** (low-pass 1-pole) has a slope of 6 dB/Oct, **LP2** (low-pass 2-pole) has a slope of 12 dB/Oct, and **LP4** (low-pass 4-pole) has a slope of 24 dB/Oct.
- **Res:** Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequency to become more pronounced.
- **Freq:** Adjusts the cutoff frequency of the low-pass filter. Frequency content above the cutoff frequency is attenuated, creating a darker sound.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's cutoff frequency follows the MIDI pitch.
- **Gain:** Adjusts the input level and increases the amount of saturation applied to the signal.
- **FM:** Adjusts the amount of audio rate modulation applied to the filter frequency, also called filter FM (frequency modulation). The FM source needs to be connected to the FM bus on the Routing page, otherwise the **FM** control will not have an effect.

Blue Monark

This multi-mode filter is a polyphonic adaptation of the filter found in NI's Monark, with additional modes and slightly different non-linear behavior. Its defining characteristic is the ability to drive the filter into saturation using the **Gain** control. Additionally, it offers audio-rate modulation of the filter frequency and is capable of self-oscillation. Feedback can be patched in a flexible manner on the Routing page. The filter has a warm and fat character that makes it suitable for overdriven bass sounds as well as classic leads.

Blue Monark contains the following parameters and controls:

- **Filter mode:** Selects one of seven modes (LP1, LP2, LP4, BP, Peak, HP, Dual Notch) that determine the response and steepness of the filter. Three low-pass modes are available, each attenuating frequency content above the cutoff frequency with the given slope. **LP1** (low-pass 1-pole) has a slope of 6 dB/Oct, **LP2** (low-pass 2-pole) has a slope of 12 dB/Oct, and **LP4** (low-pass 4-pole) has a slope of 24 dB/Oct. **BP** (band-pass) mode attenuates frequency content above and below the cutoff frequency. **Peak** mode adds a resonant filter peak at the cutoff frequency. **HP** (high-pass) mode attenuates frequency content below the cutoff frequency. **Dual Notch** mode attenuates frequencies in two narrow frequency bands (or notches) around the cutoff frequency.
- **Freq:** Adjusts the cutoff frequency of the filter. The effect of this control on the sound depends on the selected filter mode. For more information, refer to **Filter mode** above.
- **Res:** Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequency to become more pronounced.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's cutoff frequency follows the MIDI pitch.

- **Gain:** Adjusts the input level and increases the amount of saturation applied to the signal.
- **FM:** Adjusts the amount of audio rate modulation applied to the filter frequency, also called filter FM (frequency modulation). The FM source needs to be connected to the FM bus on the Routing page, otherwise the **FM** control will not have an effect.

Comb

The Comb filter works differently from an analog filter; it delays the input signal and feeds it back onto itself, similar to an echo effect. However, the Comb is optimized for very short delay times, causing interferences in the audible range. This creates regularly spaced peaks and troughs in the frequency response, resembling the appearance of a comb. The effect gets more pronounced as feedback is increased. The Comb can be used as a tuned resonator in physical modeling, a complex filter for oscillator signals, or to create flanging effects. Instead of a typical filter frequency control with adjustable key tracking, it features the same Pitch control as found on the oscillators. This way, the incoming MIDI pitch is perfectly tracked, which facilitates its applications as a tuned resonator and complex harmonic filter.

Comb contains the following parameters and controls:

- **Filter mode:** Selects one of three modes (Exciter, OSC, Flanger) that cater to different applications. **Exciter** is suitable for using Comb as a resonator in physical modeling (for example Karplus-Strong synthesis). This is done by setting the Comb filter into oscillation with a suitable signal, for example from the Exciter envelope via the Routing page's Modulation Sources, or the Noise source controlled by an envelope. **OSC** is suitable for using the Comb filter with periodic signals produced by an oscillator to create complex harmonic filtering effects. This mode compensates for resonance boosts caused by the harmonic frequencies of the oscillator signal. **Flanger** is suitable when using Comb as a flanging effect with a wide range of different signals.
- **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determine the response of the Comb in relation to incoming MIDI pitch. In **Keytrack** mode, the pitch is locked to the main MIDI pitch. **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic. **Fix** mode sets the fixed tuning of the Comb, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).
- **Pitch:** Adjusts the tuning of the Comb in semitones and cents. The **Pitch** can be modulated to produce vibrato and arpeggio effects by routing a modulation source to either of the two modulation slots below. In technical terms, the tuning adjusts the size of the delay buffer inside of the Comb. A larger delay buffer causes a longer delay time, which results in a lower filter frequency. A smaller delay buffer causes a shorter delay time, which results in a higher filter frequency.
- **FBW:** Switches between two different pickup points for the output in the signal flow. When off, the output is picked up after the delay. When activated, the output is picked up before the delay. This setting only takes effect in combination with specific configurations on the Routing page, for example when using the **FB** modules for external feedback around the Comb filter or when mixing the Comb filter's output signal with the input signal as part of a parallel routing.
- **Feedback Polarity:** Switches between positive and negative polarity for the feedback signal. With positive feedback polarity the Comb filter produces all harmonics, while with negative feedback polarity it produces only odd harmonics.
- **FB:** Sets the level of the internal feedback loop of the Comb. Higher settings increase the feedback level, resulting in a stronger resonance of the filter.
- **AP Freq:** Adjusts the frequency of an all-pass filter in the Comb's feedback path. By changing the all-pass filter frequency, you can use the Comb to produce inharmonic spectra.
- **LP Freq:** Controls the cutoff frequency of a low-pass filter in the feedback path. Decreasing the low-pass filter frequency attenuates the high-frequency content of the feedback signal, resulting in a dampened sound.

Creak

Creak is an experimental filter that stems from research into flangers. It produces strong resonances in the frequency spectrum and is characterized by its distinct non-linear behavior. Combined with the feedback loop on the Routing page, you can apply heavy distortion and spectral transformation to a sound. The filter has an aggressive and wild character that makes it suitable for radical sound design.

Creak contains the following parameters and controls:

- **Filter mode:** Selects one of four unique modes (Driven, Gnarl, Nosy, Euer). **Driven** and **Gnarl** produce different sets of harmonically spaced resonances similar to a flanger, **Nosy** produces formants with a nasal quality, and **Euer** produces formants with a vocal quality.
- **Freq:** Adjusts the frequency of the filter. Unlike a typical cutoff control, it shifts the resonances across the frequency spectrum without attenuating broad frequency bands.
- **Res:** Adjusts the intensity of the resonances in the frequency spectrum produced by the filter.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's frequency follows the MIDI pitch.
- **Mix:** Blends between the input signal and the filtered signal.

Groian

Groian is a hybrid between a filter and a flanger. It features a delay with feedback in the filter's resonance path. This structure produces strong resonances in the frequency spectrum that are superimposed with the basic response of the filter. Combined with the feedback loop on the Routing page you can apply heavy distortion and spectral transformation to a sound. Self-oscillation is possible, however it becomes unstable towards lower frequencies. The filter has a highly resonant character that makes it suitable for creating vocal or even metallic sounds.

Groian contains the following parameters and controls:

- **Filter mode:** Selects one of four modes (LP4, BP, Peak, HP) that determine the response of the filter. **LP4** (low-pass 4-pole) mode attenuates frequency content above the cutoff frequency with a slope of 24 dB/Oct. **BP** (band-pass) mode attenuates frequency content above and below the cutoff frequency. **Peak** mode adds a resonant filter peak at the cutoff frequency. **HP** (high-pass) mode attenuates frequency content below the cutoff frequency.
- **Freq:** Adjusts the cutoff frequency of the filter. The effect of this control on the sound depends on the selected filter mode. For more information, refer to **Filter mode** above.
- **Res:** Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequency to become more pronounced.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's frequency follows the MIDI pitch.
- **Character:** Adjusts the intensity of the additional resonances in the frequency spectrum produced by the delay in the resonance path.
- **FM:** Adjusts the amount of audio rate modulation applied to the filter frequency, also called filter FM (frequency modulation). The FM source needs to be connected to the FM bus on the Routing page, otherwise the **FM** control will not have an effect.

The behavior of the filter is sensitive to the level of the input signal with stronger self-oscillation at lower input levels.

Scanner

This multi-mode filter is inspired by the raw sound of a number of analog monophonic synthesizers from the 80s. Its defining characteristic is the pronounced resonance behavior, which you can use to carve out the harmonics of a signal when doing filter sweeps. Strong non-linear properties add harmonic distortion to the resonance. The filter has a dirty character that makes it suitable for adding texture and character to stacked pads and leads.

Scanner contains the following parameters and controls:

- **Filter mode:** Selects one of four modes (LP1, LP2, BP2, Peak) that determine the response of the filter. Two low-pass modes are available, each attenuating frequency content above the cutoff frequency with the given slope: **LP1** (low-pass 1-pole) with a slope of 6 db/Oct and **LP2** (low-pass 2-pole) with a slope of 12 db/Oct. **BP2** (band-pass 2-pole) attenuates frequency content above and below the cutoff frequency with a slope of 12 db/Oct. **Peak** mode adds a resonant filter peak at the cutoff frequency.
- **Freq:** Adjusts the cutoff frequency of the filter. The effect of this control on the sound depends on the selected filter mode. For more information, refer to **Filter mode** above.
- **Res:** Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequency to become more pronounced.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's frequency follows the MIDI pitch.
- **Gain:** Adjusts the input level and increases the amount of saturation applied to the signal.
- **FM:** Adjusts the amount of audio rate modulation applied to the filter frequency, also called filter FM (frequency modulation). The FM source needs to be connected to the FM bus on the Routing page, otherwise the **FM** control will not have an effect.

The behavior of the filter is sensitive to the level of the input signal with stronger self-oscillation at lower input levels.

SVF

This multi-mode filter is based on the popular state-variable filter topology and serves as a tool for a wide range of filtering tasks. Its defining characteristic is the controlled behavior and universal applicability. The filter has a clean character that makes it suitable for any sound that requires tonal shaping without adding color or distortion.

SVF contains the following parameters and controls:

- **Filter mode:** Selects one of five modes (LP2, LP4, BP, Peak, HP) that determine the response of the filter.
 - **LP2** (2-pole low-pass) mode attenuates frequency content above the cutoff frequency with a slope of 12 dB/Oct.
 - **LP4** (4-pole low-pass) mode attenuates frequency content above the cutoff frequency with a slope of 24 dB/Oct.
 - **BP** (band-pass) mode attenuates frequency content above and below the cutoff frequency with a slope of 6 dB/Oct.
 - **Peak** mode (a band-pass filter mixed with the input signal) adds a resonant filter peak at the cutoff frequency.
 - **HP** (high-pass) mode attenuates frequency content below the cutoff frequency with a slope of 12 dB/Oct.

- **Freq**: Adjusts the cutoff frequency of the filter. The effect of this control on the sound depends on the selected filter mode. For more information, refer to **Filter mode** above.
- **Res**: Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequency to become more pronounced.
- **KTR**: Adjusts the amount of key tracking, which is the degree to which the filter's cutoff frequency follows the MIDI pitch.
- **Res Boost**: Increases the range of the **Res** control to allow for a stronger resonance.

You can use the Exciter envelope via the Modulation sources on the Routing page to briefly trigger self-oscillation of the SVF at high **Res** settings. This so called filter pinging produces a damped sine wave that can be played via MIDI by using key tracking (**KTR**).

SVF Parallel

This dual multi-mode filter is based on the popular state-variable filter topology and serves as a tool for a wide range of filtering tasks. The two filters are arranged in a parallel configuration, meaning the input signal is sent to both of them separately, while the output signal is the sum of their individual outputs. Its defining characteristic is the controlled behavior and universal applicability. The filter has a clean character that makes it suitable for any sound that requires tonal shaping without adding color or distortion. Due to the parallel configuration of two filters, it is capable of producing vocal formants as well as complex wobble sounds.

SVF Parallel contains the following parameters and controls:

- **Filter mode:** Selects one of seven modes that combine different responses of each of the two parallel filters. Six combinations of a 12 dB/Oct **LP** (low-pass) filter, a 12 dB/Oct **HP** (high-pass) filter, and a 6 dB/Oct (**BP**) (band-pass) filter are available, as well as the special Plateau mode.
- **Freq:** Adjusts the cutoff frequencies of the two parallel filters. Both cutoff frequencies are offset by the same amount. Their relative position in the frequency position is set with the **Bandwidth** control.
- **Res:** Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequencies to become more pronounced.
- **Bandwidth:** Spreads the cutoff frequencies of the two parallel filters in the frequency spectrum. At minimum setting, both filters share the same cutoff frequency, which makes the resonance much more pronounced. As **Bandwidth** is increased, the cutoff frequency of one filters moves down in frequency, while the other moves up. This way you can distribute the filter resonances to create formant frequencies.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's cutoff frequency follows the MIDI pitch.
- **2nd Filter:** Blends between single and dual configurations of the filter by mixing in the second filter and adjusting the amount of frequency spread introduced by the **Bandwidth** control.

You can use the Exciter envelope via the Modulation sources on the Routing page to briefly trigger self-oscillation of the SVF Parallel at high **Res** settings. This so called filter pinging produces damped sine waves that can be played via MIDI by using key tracking (**KTR**).

SVF Serial

This dual multi-mode filter is based on the popular state-variable filter topology and serves as a tool for a wide range of filtering tasks. The two filters, a high-pass and a low-pass, are arranged in a serial configuration, meaning the input signal is sent to the high-pass filter, the output of which is going into the low-pass filter. Its defining characteristic is the controlled behavior and universal applicability. The filter has a clean character that makes it suitable for any sound that requires tonal shaping without adding color or distortion. Due to the serial configuration of two filters, it is capable of producing vocal formants as well as balancing the overall tonal quality of a sound.

SVF Serial contains the following parameters and controls:

- **Freq:** Adjusts the cutoff frequencies of the two serial filters. Both cutoff frequencies are offset by the same amount. Their relative position in the frequency position is set with the **Bandwidth** control.
- **Res:** Adjusts the resonance amount of the low-pass filter. Turning **Res** to the right increases the resonance, causing the frequency content at the cutoff frequencies to become more pronounced.
- **Bandwidth:** Spreads the cutoff frequencies of the two serial filters in the frequency spectrum. At minimum setting, both filters share the same cutoff frequency. As **Bandwidth** is increased, the high-pass filter's cutoff moves down in frequency, while the low-pass filter's cutoff moves up. This way you can distribute the filter resonances to create formant frequencies.
- **KTR:** Adjusts the amount of key tracking, which is the degree to which the filter's cutoff frequency follows the MIDI pitch.
- **HP Peak:** Gradually turns the high-pass filter into a peak filter (a band-pass filter mixed with the input signal) with only a resonant peak but no filter slope. This way you can add formant frequencies without filtering out the rest of a signal.
- **LP Peak:** Gradually turns the low-pass filter into a peak filter (a band-pass filter mixed with the input signal) with only a resonant peak but no filter slope. This way you can add formant frequencies without filtering out the rest of a signal.

You can use the Exciter envelope via the Modulation sources on the Routing page to briefly trigger self-oscillation of the SVF Serial at high **Res** settings. This so called filter pinging produces damped sine waves that can be played via MIDI by using key tracking (**KTR**).

14. Insert effects

There are two different effects sections available in Massive X; Insert Effects and Stereo Effects. Insert Effects can be used as parts of the polyphonic voice structure, while Stereo Effects are used on the voice mix at the final stage of the signal chain. This chapter will cover the Insert Effects section, including all available modules, their respective controls and suggestions for best use.

i This feature is not available in Massive X Player.

Selecting where to place the Insert Effects in the signal chain is done via the Routing page. The three Insert Effects are represented by circular icons (**A, B, C**).

Individually, they can be placed anywhere in the voice structure. They can also be chained together, or inserted separately on any sound source. Where you choose to place the effect in the signal path will have significant impact on the final sound and the way the effect behaves. These crucial sonic differences will become obvious as you experiment with different routing options and effects combinations.

The following section provides an overview of the Insert Effects section:

1. **Insert Effect On/Off:** Switches the Insert Effect on and off. Use this switch to bypass the effect for A/B comparison. The icon can also be found on the Insert Effect module on the Routing page.
2. **Insert Effect Menu:** Selects an Insert Effect for the respective slot. Three slots are available, called **A**, **B**, and **C**. The effect panel on display is highlighted with an underline. You can show the other effect panels by clicking on the corresponding Insert Effect menu.
3. **Parameter Controls:** This area hosts a range of buttons and knobs that control different parameters of the effect. Each Insert Effect has a different selection of controls that relate to its behavior and operation.

Anima

Anima can be used to enhance oscillator signals by altering their frequency content. The results range from subtle colorization to harmonic transformations that are achieved by adding new sidebands in the frequency spectrum.

As an experimental derivative of effects like comb filters and flangers, its internal structure involves a unique combination of delay lines, audio rate modulation, and feedback. Similar to tuned comb filters, Anima tracks the MIDI pitch of the instrument. This way, it can be tuned relative to the pitch of the input signal, allowing you to explore a range of interesting sounds.

Anima contains the following parameters and controls:

- **Pitch:** Adjusts the center frequency of the tuned delay lines in Anima's internal structure.
- **Mix:** Blends between the input signal and the effect signal. Turn the control fully left to bypass the effect, or right to mix in the effect. Anima is commonly used with high to maximum **Mix** settings.
- **FB:** Adjusts the amount of feedback in Anima's internal structure. Anima is commonly used with high to maximum **FB** settings.

- **+/-**: Selects one of two routing modes of the effect and **(+)** and **(-)**. A positive polarity setting is represented by the **(+)** icon and is the default setting. Press the icon to change to a negative polarity **(-)**. Each of the two modes features a unique set of signal polarities within Anima's internal structure. This parameter has a strong influence on the overall sound character of the effect.
- **Smear**: Adjusts the distribution of tuned delay lines around the center frequency as set with **Pitch**.
- **Amount**: Adjusts the amount of internal modulation applied to the tuned delay lines.
- **Rate**: Sets the rate of the internal modulation oscillator.
- **Fast/Slow**: Selects one of two basic modes (Slow, Fast). When **Slow** is selected, the internal modulation oscillator runs at LFO rates. This produces sounds reminiscent of a comb filter combined with vibrato. When **Fast** is selected, the internal modulation oscillator runs at audio rates, relative to the instrument's MIDI pitch. This produces interesting harmonic transformations by adding new sidebands in the frequency spectrum, similar to frequency modulation or phase modulation.

Bass Enhancer

The Bass Enhancer module is a specialized bass enhancement effect that brings presence and drive to low frequency content. The X-Freq control adjusts the cutoff frequency of the crossover filter, splitting the signal into high and low bands. This allows you to apply saturation and compression to the low band, whilst leaving the high band unaffected.

The Bass Enhancer contains the following parameters and controls:

- **X-Freq**: Adjusts the cutoff frequency in a range of 40 Hz to 200 Hz. Frequency content below the cutoff frequency is amplified.
- **Mix**: Blends between the input signal and the effect signal. Turning the control from left to right mixes in the effect signal.
- **Gain**: Adjusts the input level in a range of -15 dB to +15 dB.

- **Level:** Adjusts the output level in a range of -6 dB to +6 dB.
- **Boost:** Activates the internal saturation stage, adding harmonics to the signal.

Bit Crusher

The Bit Crusher degrades a signal by reducing the bit depth, which is the number of bits used to represent amplitude in digital audio. A high bit depth results in an accurate representation of a signal, while a low bit depth adds noise and distortion. This can be used for lo-fi effects ranging from subtle noise textures to extreme distortion that turns any signal into clicks and pulses.

The Bit Crusher contains the following parameters and controls:

- **Crush:** Adjusts the bit depth and therefore the strength of the bit reduction effect. By turning the control fully left, the lowest number of bits is used, resulting in the strongest effect. By turning the control fully right, the highest number of bits is used, closely resembling the input signal.
- **Mix:** Blends between the input signal and the effect signal. Turn the control fully left to bypass the Bit Crusher, or turn right to mix in the effect. Turning the control fully right results in a wet only signal.
- **Offset:** Adds an offset to the input signal, making it asymmetric. This can be used to create variations of the basic bit reduction effect.
- **Norm:** Subtracts the input signal from the effect signal, making the bit reduction effect more pronounced.
- **HQ:** Activates high quality anti-aliasing. By default, **HQ** is deactivated. Press the **HQ** button for less harsh, smooth lo-fi results.

Distortion

This module offers different nonlinear distortion functions that are especially useful for polyphonic sound design. Nonlinear distortion is produced when the output of a signal is not exactly proportional to the input signal, generating harmonics. The Distortion provides five modes for different nonlinear functions, Mix and Drive controls and a HQ button that activates high quality anti-aliasing. Unlike the Stereo Effects' Nonlinear Lab module, the Distortion does not offer internal memorizing, loading or cabinet simulation.

The Distortion contains the following parameters and controls:

- **Mode:** Selects one of five modes that offer different nonlinear functions (tanH, hypB, sin C, H.clip, Rectify). Each mode is visually represented below the Mode selector.
- **Mix:** Blends between the input signal and the effect signal. Turn the control fully left to bypass the effect, or right to mix in the distortion.
- **Drive:** Controls how hard the saturation stages are driven, from subtle to extreme.
- **HQ:** Enables antialiasing in order to improve the audio quality of the nonlinear functions.

i Enabling **HQ** introduces half a sample latency, which can cause phase artifacts when mixed with the original signal. This can also have consequences when used in feedback loops created with audio routing.

Folder

Sitting somewhere between saturation and hard sync effect, the Folder starts to fold, or copy, the waveform of the input signal when driven with high pre-amplification settings. The sonic results are varied and dependant on the input signal, the selected Mode and the Drive and Offset settings. Four modes (Sinus, Triangle, Wrap, Spiky) determine the character of the folding, from smooth to distinctly rough. The harmonic repetitions can to create sounds reminiscent of hard sync-style effects, which you can incorporate subtly with low Mix settings, or turn up for an intense, brutal sound. The Folder can also share sonic correlations to phase modulation sounds. This is achieved most effectively by combining a sinus input signal with Sinus mode .

The Folder contains the following parameters and controls:

- **Mode:** Select one of four modes (Sinus, Triangle, Wrap, Spiky). The wave of each mode is visually represented below the Mode selector.
- **Mix:** Blends between the input signal and the effect signal. Turn the control fully left to bypass the effect, or turn right to mix in the effect.
- **Drive:** Pre-amplifies the signal before it reaches the folding algorithm.
- **Offset:** Shifts the operating point of the algorithm.
- **HQ:** Activates high quality anti-aliasing. By default, HQ is deactivated. Press the HQ button to turn on anti-aliasing.

Frequency Shifter

The Frequency Shifter shifts the frequency of the incoming signal. Unlike a pitch shifter, the Frequency Shifter is able to create inharmonic partials from a sound comprised of harmonic partials, adding a metallic character to your sound. A Shepard phaser effect can be achieved when slow modulation and feedback is applied, with the Mix control set to 50%.

The Frequency Shifter contains the following parameters and controls:

- **Range:** Selects one of two frequency ranges (Wide, Narrow). **Wide** makes the Frequency Shifter operate over a wide frequency range, useful for achieving wild and animated sounds. The **Narrow** setting provides good control for relatively small shifting factors. This range is scaled with the **Freq** control.
- **Mix:** Blends between the input signal and the effect signal. Turn the control fully left to bypass the effect, or right to mix in the effect.
- **Freq:** Shifts the partials of a signal. In centre position, the effect is neutral. Turning the control right shifts the partials upwards, and turning left shifts the partials downwards. Due to the nature of the algorithm, partials can be reflected upwards again, if the downshifted partials are exceeding zero hertz. The encoder itself behaves in a nonlinear manner, resulting in a finer resolution around the centre.
- **FB:** Adjusts the amount of feedback. When this control is turned up, the output of the Frequency Shifter is reflected back in to the input, creating a Shepard flanger effect.

Insert Oscillator

The Insert Oscillator (OSC) is an independent source for three classic synth waveforms; Sine, Sawtooth, and Pulse, which can be used in addition to the main Wavetable Oscillators. When used simultaneously over the three Insert Effects slots and alongside the two Wavetable Oscillators, it expands to a five oscillator synthesizer. These Insert Oscillators can also be phase locked to either Wavetable Oscillator, creating a classic Sub Oscillator. The Insert Oscillator is one of the most powerful tools in the Insert Effects, greatly expanding the potential of the Massive X synth engine.

The Insert Oscillator contains the following parameters and controls:

- **Mode:** Selects the waveform of the oscillator (Sine, Saw, Pulse). **Sine** and **Saw** modes offer a phase shift control while **Pulse** mode offers control over PW (pulse width).
- **Invert:** Inverts the polarity of the waveform. When the button is activated, the waveform is flipped.
- **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determines the response of the oscillator in relation to incoming MIDI pitch. In **Keytrack** mode, the pitch is locked to the main MIDI pitch. **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic. **Fix** mode sets the fixed tuning of the oscillator, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).
- **Pitch:** Adjusts the tuning of the oscillator in semitones and cents. The **Pitch** can be modulated by routing a modulation source to either of the two modulation slots below, allowing you to produce vibrato and arpeggio effects.
- **Lock:** Enables you to lock the pitch to one of the main Wavetable oscillators. When inactive, the pitchbox is shown, providing Massive X's standard oscillator tuning. When the **Lock** button is active, settings for **Ratio** and the Sync source are provided.
 - **Lock Ratio:** Selects one of four ratios (1:1, 1:2, 1:3, 1:4) that determines the Tune Ratio in relation to the chosen Source oscillator. At **1:1**, the Insert oscillator runs at exactly the same pitch as the Source oscillator. With a **1:2**, the Insert oscillator is 1 octave lower (-12 semitones). **1:3** runs the Insert oscillator at 1/3 of the speed, equating to approximately 1 octave and a fifth lower (-19 semitones). At **1:4**, the Insert oscillator runs 2 octaves lower (-24 semitones).
 - **Pitch Source:** Selects if the pitch should be locked to Wavetable oscillator 1 or 2. The **Ratio** cannot be modulated as it is hard-locked to the Source oscillator, but modulation can be applied to the Insert oscillator's **Phase/PW** parameter.

- **Phase/PW:** The label and functionality of this control changes according to the selected mode. Sine and Sawtooth modes offer a **Phase** offset control, allowing you to phase shift the oscillator. The Phase control is used to set the Phase relationship between oscillators when locked to the Wavetable oscillators or if the Engine is set to resetting behaviour on the Voice page. When Pulse is selected, the **Phase** control switches to **PW**, which adjusts the width of the Pulse wave. When set to the center value, a square wave is produced. Adjusting the **PW** control makes the Pulse wave asymmetric, introducing even harmonics that create a thinner sound. Applying modulation to the **PW** parameter is a classic technique used to add dynamism to a waveform, known as PWM (pulse width modulation).
- **Mix:** Blends between the input signal and the independently delivered waveform. Turn the control fully left to bypass the effect, or turn right to mix in the waveform. The Mix control has the same functionality across all modes.

PM Oscillator

The Phase Modulation oscillator features a sine wave oscillator that can be Phase modulated by it's input signal and placed anywhere in the voice structure. The rich phase modulated audio signal can be mixed in with the original input. Combining the three Insert Effects with the two Wavetable oscillators, creates the potential for a seven operator FM synth.

Complex Wavetable oscillators can be used to modulate the operators, or the operators can be used to phase modulate the Wavetable oscillators via the Aux bus. You can even combine it with filters, ring modulation or any other Insert Effects. With flexible routing, you can achieve cross-feeding of operators or phase feedback chains within itself.

The PM Oscillator contains the following parameters and controls:

- **Invert:** Inverts the polarity of the waveform. When the button is activated, the waveform is flipped.

- **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determines the response of the oscillator in relation to incoming MIDI pitch. In **Keytrack** mode, the pitch is locked to the main MIDI pitch. **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic. **Fix** mode sets the fixed tuning of the oscillator, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).
- **Pitch:** Adjusts the tuning of the oscillator in semitones and cents. The **Pitch** can be modulated by routing a modulation source to either of the two modulation slots below, allowing you to produce vibrato and arpeggio effects.
- **PM:** Adjusts the Phase Modulation amount. This works as an amplifier for the incoming signal added to the sine oscillator's phase.
- **Mix:** Blends between the input signal and the sine operator signal. Turn the control fully left to bypass the effect, or turn right to mix in the waveform.

Ring Modulator

Ring modulators mix the frequencies of two different waveforms, and output the sum and difference of the frequencies present in each. This process of ring modulation produces a signal rich in partials. Neither original signals are prominent in the final output, allowing you to transform your signal.

The Ring Modulator offers a Sine wave oscillator that can be used to ring modulate any input signal. This can be freely placed into the voice structure via the Routing page like any other Insert effect. Using ring modulation with one of the main oscillators, when the two frequencies are not harmonically related, can create metallic or bell-like sounds.

The Ring Modulator contains the following parameters and controls:

- **Invert:** Inverts the polarity of the waveform. When the button is activated, the waveform is flipped.

- **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determines the response of the oscillator in relation to incoming MIDI pitch. In **Keytrack** mode, the pitch is locked to the main MIDI pitch. **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic. **Fix** mode sets the fixed tuning of the oscillator, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).
- **Pitch:** Adjusts the tuning of the oscillator in semitones and cents. The **Pitch** can be modulated by routing a modulation source to either of the two modulation slots below, allowing you to produce vibrato and arpeggio effects.
- **Mix:** Blends between the input signal and the sine waveform. Turn the control fully left to bypass the effect, or turn right to mix in the waveform.

Sample and Hold

The Sample and Hold module provides the opportunity for classic Sample and Hold effects. The internal oscillator samples the incoming signal, holding this value until the next sample is taken. This effect results in a 'stepped' quantized audio signal. The oscillator itself is not heard directly, but can be tuned in the same way as the other oscillators. The Sample and Hold effect can be used to create a range of different distortion effects. Try setting low Pitch values to recreate the sounds of old digital synthesizers. For classic sample rate reduction, Key Tracking must be deactivated.

The Sample and Hold module contains the following parameters and controls:

- **HQ:** When deactivated, the effect operates in a typical way with a clear digital character. When activated, a high quality algorithm treats the steps in the waveform caused by downsampling, producing an analog sound.
- **Pitch Mode:** Selects one of three modes (Keytrack, Fix, Ratio) that determines the response of the oscillator in relation to incoming MIDI pitch. In **Keytrack** mode, the pitch is locked to the main MIDI pitch. **Ratio** mode multiplies or divides the MIDI pitch in relation to the ratio setting. For example, a ratio of 3 adjusts the pitch to 3 times the frequency, producing the 3rd harmonic. **Fix** mode sets the fixed tuning of the oscillator, disregarding the incoming MIDI pitch. This mode displays MIDI note numbers, with the default set to 60 (middle C).

- **Pitch:** Adjusts the tuning of the oscillator in semitones and cents. The **Pitch** can be modulated by routing a modulation source to either of the two modulation slots below, allowing you to produce vibrato and arpeggio effects.
- **Mix:** Blends between the input signal and the delayed signal. Turn the control fully left to bypass the effect, or turn right to mix in the delayed signal.

Track Delay

Track Delay operates unlike a standard delay effect. The module provides two basic modes of operation. In Key Track mode the input signal can be shifted in relation to MIDI pitch, and mixed with the original signal, in an inverted or normal manner. For example, a saw input can be transformed into a square wave by phase shifting the signal by 180 degrees and subtracting the inverted mix from the input. Modulating the Phase results in true PWM (pulse width modulation), and this can be adapted to any input signal as WM. Fix mode can be used to mimic pickup effects, placing the pickup on a virtual string. Track Delay can also be used as a polyphonic chorus effect.

The Track Delay contains the following parameters and controls:

- **Modes:** Selects one of two modes (Key Track, Fix) that define the main operating mode. In **Key Track** mode, the delay time is locked to the main MIDI pitch. In **Fix** mode, the delay time is not locked to the main MIDI pitch and operates in the time domain. The range is determined by the **Range** menu.
- **Range:** Selects one of three options for each of the two operating modes (**180°/10msec**, **360°/50msec**, **720°/150msec**) phase degree/milliseconds.
- **Phase:** Adjusts the **Phase** when **Key Track** mode is selected. In **Fix** mode, it determines the delay time.
- **Mix:** Blends between the input signal and the delayed signal. Turn the control fully left to bypass the effect, or right to mix in the delay signal. Center position is recommended. At this position, the **Trim** encoder can be used to control the center level.
- **Invert:** Switches between Normal and Invert to determine how the delayed signal is mixed. An Inverted polarity is recommended.

- **Lag:** Adjusts the smoothing of delay time changes.
- **Trim:** When the **Mix** encoder is set to center position, the **Trim** knob controls the center level.

Utility

This module helps you correct, level out, or finalize your sound. If a sound is too bright, too bass heavy, too loud or soft, this is the tool to use. It is especially effective when used in conjunction with the Tracker, as well as in Feedback scenarios, where it can be used together with the Comb filter to create an overblown flute and similar effects. This enables you to scale the amplitude in order to produce a balanced sound over the range of the keyboard. The filters have no nonlinearities or resonance, resulting in a clean and neutral sound.

The Utility contains the following parameters and controls:

- **Filter Type:** Two menus that offer four filter types (**HP1**, **HP2**, **LP1**, **LP2**) to select from. If you use two **LP2** filters with the same settings you will achieve a 4-pole filter characteristic.
- **Freq:** Determines the cutoff frequency for the corresponding filters.
- **Level:** Sets the volume of the VCA (voltage controlled amplifier). Two controls determine the behavior of the VCA:
 - **Range:** Defines the maximal amplification factor that can be achieved with the VCA. Turning the control from fully counter-clockwise to centre position provides a range from 1% to 100%. Turning **Range** from the center position to fully right provides a maximum of 500%.
 - **Curve:** Bends the response character of the VCA. At centre position, the VCA behaves linearly. This is the default setting for this module. Turned fully left, it produces a strong bend with the amplification factor rising exponentially towards the end. At full right position, it bends strongly in the opposite way, so the amplification factor rises logarithmically towards the end.

15. Amplifier

i This feature is not available in Massive X Player.

The Amp (Amplifier) is the final module in the signal path of the voice. It controls the level and panning before the signal enters the Stereo Effects section. The Amp Envelope (E1) is hard-wired to control the Amp level. The Level control can be used to adjust the signal level going into the Stereo Effects, while the Pan control is used to distribute the sound to the left or right stereo channel and can also be modulated for creative panning effects.

The additional FB control adjusts the amount of feedback through the voice's feedback loop. The feedback loop can be freely connected in the Polyphonic Area of the Routing page. For more information about the feedback loop, refer to [Feedback loop](#).

Amplifier overview

The Amp section contains the following parameters and controls:

1. **Level:** Adjusts the output level of the amplifier. Double-click to reset to the default value.
2. **Pan:** Distributes the sound to the left or right stereo channel. Double-click to reset to the default value.
3. **High-pass Filter** (HPF icon): Enables a high-pass filter that cuts low-frequency content in the feedback loop. When activated, you can avoid overloading the feedback loop with excessive bass.

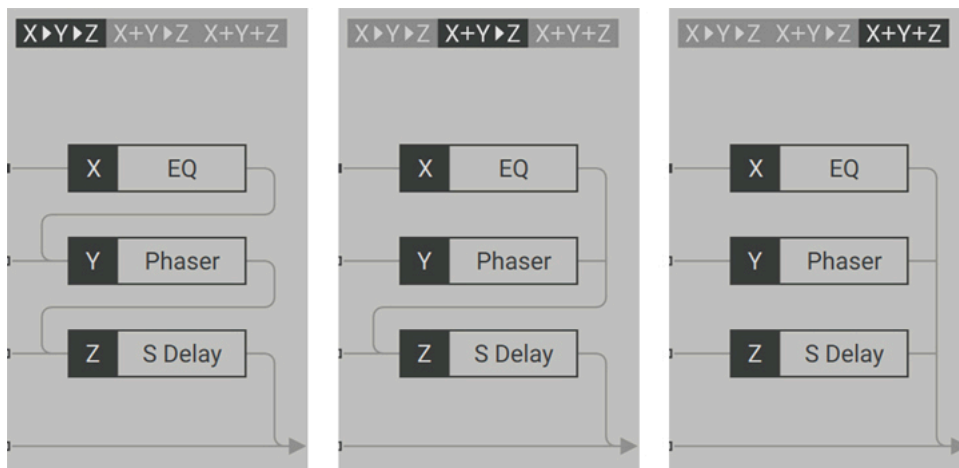

4. **FB** (Feedback): Adjusts the level or volume of the feedback loop. This way you can control the chaotic behavior and distortion produced by the feedback.

16. Stereo effects

Stereo Effects are the final stage that the signal passes through before reaching the main output. A wide range of effects are offered, from time-based effects like flanging, phasing and chorus, to spatial effects that allow you to adjust and expand the stereo field. An over-the-top compressor lets you radically shape the dynamics of your sound. Versatile distortion, saturation and overdrive effects can be produced, and combined with a true stereo reverb or delay.

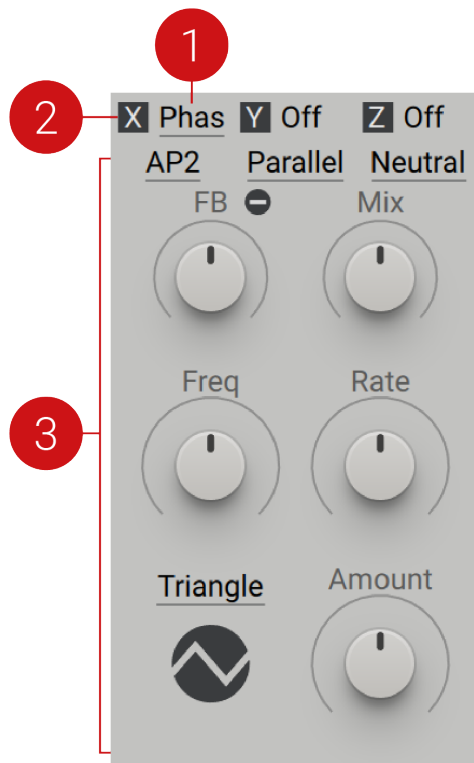

i This feature is not available in Massive X Player.

Effects can be loaded into three slots: **X**, **Y**, and **Z**. Three routing options offer different ways for the effects to be mixed: **X > Y > Z** chains the three effects, **X + Y > Z** sends the sum of the X and Y effects to the Z effect, and **X + Y + Z** sums all three effects. For more information on routing, refer to [Routing page overview](#).

The three Stereo Effects routing options

The following section provides an overview of the Stereo Effects section:

1. **Stereo Effect selector:** Shows the name of the Stereo Effect loaded in that slot, or **Off** if the slot is empty. Three slots are available, called **X**, **Y**, and **Z**. The selected slot is highlighted with an underline and its effect parameters appear in the panel below. You can click this underlined name to open a menu and load another Stereo Effect into that slot, or click the selector of another slot to display its parameters below.
2. **Stereo Effect On/Off:** Switches the Stereo Effect on or off. You can use this to bypass the effect for A/B comparison. This icon can also be found on the Stereo module on the [Routing page](#).
3. **Effect panel:** Shows the parameters of the Stereo Effect in the highlighted slot (its name is underlined above). Each Stereo Effect has a distinct set of parameters.

Dimension Expander

The Dimension Expander is a Chorus with stereo expansion capabilities, that can add an extra dimension to your sound. The results range from subtle enrichment to a shimmery, expanded stereo sound.

The Dimension Expander contains the following parameters and controls:

- **Modes:** Selects one of four modes of the effect (1 - 4), ranging from subtle to strong.
- **Amount:** Adjusts the strength of the effect.
- **Bright:** When on, the character is neutral. When off, the effect produces a slightly filtered sound.
- **Stereo:** Morphs the output of the device from mono to stereo. Turn the control fully right for a complete stereo effect.

Equalizer

The Equalizer is used to balance and shape the frequency content of a sound. Internal algorithms make this equalizer sound particularly musical.

The Equalizer contains the following parameters and controls:

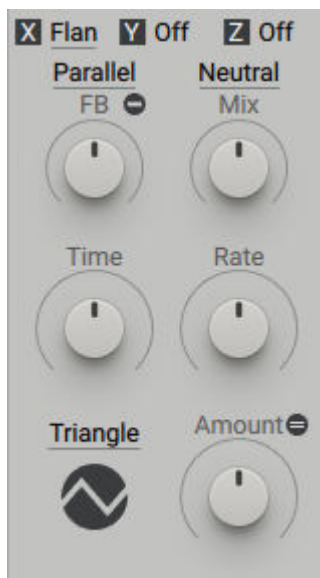

- **Freq:** Sets the frequency of the high shelf filter (1.2kHz to 23.6kHz).
- **Hi-Gain:** Adjusts the level control of the high shelf filter (-24dB to +24 dB). Center position is 0dB.

- **Freq:** Sets the frequency of the parametric mid-band (90Hz to 14kHz). The center position is 2.14 kHz.
- **Mid Gain:** Controls the boost factor of the mid-band (from -24dB to +24 dB). Center position is 0dB.
- **Q:** The Quality Factor (Q) gives you control over the sharpness or bandwidth of the filter. A wide and round setting is produced when the control is turned left. Turning the control right creates a narrow resonance.
- **Low Gain:** Adjusts the level of the low shelf filter (-36dB to +18 dB). Center position is 0dB. The frequency range is dependant on the level boost, sitting between 120Hz and 260Hz.

Flanger

The Flanger is a sonically diverse module, featuring seven different play modes, ranging from classic stompbox-style to wild and complex flange effects. The delay range of a typical flanger is expanded, allowing you to also create unusual and unique effects. To achieve a classic flanger sound, the range must be chosen carefully.

The Flanger contains the following parameters and controls:

- **Modes:** Selects one of seven modes that determine the type of modulation and the internal routing of the flanger. The available parameters vary depending on the chosen mode.
 - **Parallel:** The LFO modulation is identical for the left and right channels while the audio inputs are still true stereo. This mode is best suited for the classic stompbox flanger sound.
 - **Wide:** The LFO modulation of the left and right channel is slightly offset, resulting in a wider, stereophonic sound.
 - **Inverse:** The LFO modulation is shifted by 180 degrees (inverse modulation) on one side, resulting in an even wider stereophonic sound.
 - **Difference:** The internal signals are mixed so that the output stages show the sum and the differences of this operation. This results in a sound with a metallic character, that is most clearly heard when the **Time** control is set to a short delay time. The Triangle **LFO Shape** is recommended for this mode.
 - **Cross:** The LFO uses inverse modulation. The internal signals are mixed and the output stages show the sum and the differences of this operation. As Cross mode relies on a specific, internal modulation to achieve its result, the **LFO Shape** is predefined and can not be changed. While it shares similarities to Difference mode, it creates stable frequency sidebands resulting in less movement and sonic wobble.
 - **Cross Astral:** A variation of Cross and Difference modes, using more complex internal modulation. The **LFO Shape** is fixed and the shape menu is removed. This mode can be particularly effective for raw pads or pure waveforms.
 - **Manual:** In Manual Mode, independent Time control for the left and right channels is available and the internal LFO modulation is removed. Applying different modulations to the left and right sides can produce dramatic results.
- **Mix:** Blends between the input signal and the effect signal, determining how much phasing is applied. Turn the control fully left to bypass the effect. At the center position, the largest frequency gaps are created. Turning the control fully right creates a pure flanger effect.
- **FB:** Sets the amount of signal that will feed back from the delays output into the input of the delay. The more feedback, the more the frequency peaks and gaps are modeled out of the sound spectrum.
- **FB +/-:** This switch heavily influences the overall characteristics of the flanger. It determines whether the feedback signal is mixed in with normal or inverse polarity. Negative feedback produces uneven harmonics from the comb filter circuit. Positive feedback creates even and odd harmonics. Cross and Cross Astral modes do not offer **Feedback** polarity.
- **Time:** Sets the delay time or fundamental frequency of the flanger. The LFO modulation is applied around this center frequency. In Manual mode, independent **Time** control of the left and right channels is available.
- **Rate:** Sets the Modulation Rate of the LFO.
- **LFO Shape:** Selects one of three modulation shapes (Triangle, Logarithmic, Sine). The LFO shapes are tweaked to be musical rather than mathematically perfect shapes. Besides the standard **Triangle** and **Sine** shapes, a **Logarithmic** shape is an option to recreate classic flanger sounds.
- **Amount:** Sets the amount of **Time** modulation by the LFO. Classic flange sounds can be achieved with lower **Amount** settings.
- **Constant Amount Button:** When deselected, the LFO amplification applied by the **Amount** control works in a typical manner. A faster LFO rate setting will apply stronger detuning to the comb filter. When **Constant Amount** is active, the amount of detuning applied is fixed, regardless of the LFO rate. This leads to very interesting pitch-shifting effects when using internal Triangle modulation with high **Feedback** values.

Nonlinear Lab

The Nonlinear Lab offers a multitude of overdrive and distortion characteristics. Several optional speaker cabinet simulations further expand the sonic flexibility of the Nonlinear Lab. The available parameters and controls are dependent on the chosen Drive type and Cabinet.

The Nonlinear Lab contains the following parameters and controls:

- **Drive type:** Selects one of three different HQ saturator/distortion models (Hard Clip, Soft Clip, Overdrive).

Hard Clip: A standard tanH (=hyperbolic tangent) saturator. This model offers great standard distortion that works particularly well for acidic sounds.

- **HP Pre:** Adjusts the frequency of the high-pass filter, applied to the input signal before the saturator. Use this control to avoid overloading the saturator stage with excessive bass.
- **HP Post:** Frequency of the high-pass post-stage (after saturator). Adjusts the bass output of the saturator.
- **Comp:** Adjusts the output level compensation for the **Drive** amount. The output level of different **Drive** amounts is highly dependent on the input signal. The **Comp** control helps to keep the output level under guard.

Soft Clip: The most gentle distortion mode of the Nonlinear Lab. It works well for a wide number of signals like bass, guitar, and drum sounds. This mode offers three different models of different sonic flavors.

- **HP Pre:** Adjusts the frequency of the high-pass filter, applied to the input signal before the saturator. Use this control to avoid overloading the saturator stage with excessive bass.
- **Models:** Selects one of three sub models for this mode (Glue, Warm, Hot). **Glue** offers compression with relatively subtle distortion. **Warm** offers compression with medium distortion while the **Hot** setting features compression with strong distortion.
- **Comp:** Adjusts the output level compensation for the **Drive** amount. The output level of different **Drive** amounts is highly dependent on the input signal. The **Comp** control helps to keep the output level under guard.

Overdrive: An extreme, intense distortion effect, that produces exaggerated sonic results.

- **HP Pre:** Adjusts the frequency of the high-pass filter, applied to the input signal before the saturator. Use this control to avoid overloading the saturator stage with excessive bass.
- **Inertia:** Determines how fast the loading of the stage occurs, depending on the frequency. Turn the control fully right for the fastest response.
- **Comp:** Adjusts the output level compensation for the **Drive** amount. The output level of different **Drive** amounts is highly dependent on the input signal. The **Comp** control helps to keep the output level under guard.
- **Stereo:** Selects between Mono and Stereo. In **Mono**, the left and right sides are mixed together and sent to the monophonic saturator and cabinet stages. The dry path remains stereo. In **Stereo** mode, the device operates in true stereo.
- **Drive:** Controls how hard the saturation stages are driven, from subtle to extreme.
- **Mix:** Blends between the unaltered input signal and the affected output of the Lab.
- **Cabinet Stage:** Selects one of six different guitar cabinet simulations (California, West Coast, Classy, Hi Gain, Crank, British). The cabinets drastically shape the overall color of the output. Bypass the cabinet stage by selecting **Off**. Without a cabinet selected, the distortions may sound raw and are particularly suitable for raw synth sounds.
- **Bass:** Finely adjusts the bass response and boominess of the cabinet model.
- **Vari:** Selects one of three sub-models of the cabinet (A, B, C).

Multi Compressor

The Multi Compressor is a multiband compressor providing both downward and upward compression. This effect lets you reduce the dynamic range of your sound by selectively raising soft signals and attenuating loud signals on each of the three frequency bands. The Multi Compressor is a great tool for adding punch to your sound while retaining its details.

The top part of the Multi Compressor contains global parameters that affect all three frequency bands together. By default, it shows the **main parameters**:

- **In Gain:** Adjusts the level of the signal fed into the effect, from -24 dB to +24 dB (0 dB by default).
- **Mix:** Adjusts the mix between the dry, unprocessed signal and the signal processed by the effect. At full left (0 %), you hear only the unprocessed signal. At full right (100 %), you hear only the processed signal.
- **Out Gain:** Adjusts the level of the signal after it has been processed by the effect, from -24 dB to +24 dB (0 dB by default).
- **Up:** Adjusts the amount of upward compression applied to all frequency bands, from 0 to 200 % (100 % by default).
- **Down:** Adjusts the amount of downward compression applied to all frequency bands, from 0 to 200 % (100 % by default).
- **Settings (cogwheel icon):** Switches to the [advanced parameters](#) of the Multi Compressor.

The bottom part of the Multi Compressor lets you adjust the compression applied to the high, mid, and low frequency bands. For each band a row of controls contains, from left to right:

- **H, M, or L button:** Mutes or unmutes the high, mid, or low frequency band. When a frequency band is muted, its audio is off and its controls are grayed out.
- **Brown bar:** Represents the range of levels that will be raised by the upward compression, from the minimum level (on the left) up to the specified threshold (on the right). You can click the bar to turn the upward compression on or off for that frequency band. When the compression is off, the bar is darker and audio at these levels will stay untouched.
- **Gray segment:** Represents the thresholds for both the upward compression (brown bar) and the downward compression (green bar). You can drag the segment horizontally to adjust both thresholds. For example, dragging the segment to the left will decrease the thresholds: therefore, a smaller portion of the soft signals (only the softest ones) will be raised by the upward compression, while a greater portion of the loud signals will be attenuated by the downward compression. Inversely, dragging the segment to the right will raise the thresholds, therefore a greater portion of the soft signals will be raised while a smaller portion of the loud signals (only the loudest ones) will be attenuated.

- **Green bar:** Represents the range of levels that will be attenuated by the downward compression, going from the specified threshold (on the left) up to 0 dB (the maximum level, on the right). You can click the bar to turn the downward compression on or off for that frequency band. When the compression is off, the bar is darker and audio at these levels will stay untouched.
- **Out:** Adjusts the output level of that frequency band.

Advanced parameters

Activating the cogwheel icon lets you display the advanced parameters in the top part of the Multi Compressor:

- **XLow:** Adjusts the crossover frequency between the low and mid bands. Lower values will set a narrower low-frequency band and a wider mid-frequency band, and inversely.
- **XHigh:** Adjusts the crossover frequency between the mid and high bands. Higher values will set a narrower high-frequency band and a wider mid-frequency band, and inversely.
- **Attack:** Adjusts how quickly the compression is applied once a signal exceeds the threshold. At lower values the compressor will process the signal as soon as it crosses the threshold. At higher values the compressor will let more of the signal go through before it comes into effect. For example, you can use higher attack values to retain more transients of percussive sounds.
- **Release:** Adjusts how quickly the compressor gets back to its standby state once the signal returns below the threshold (for the downward compression) or above the threshold (for the upward compression).
- **Settings (cogwheel icon):** Switches back to the [main parameters](#) of the Multi Compressor.

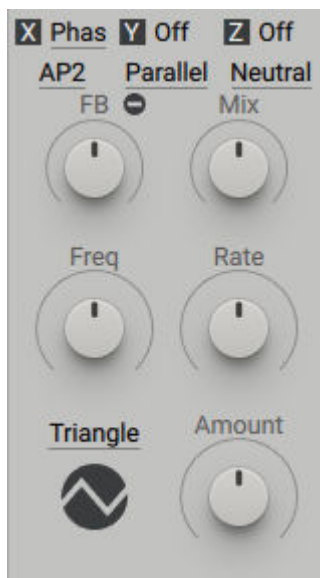

In the lower part of the Multi Compressor, the controls for the individual frequency bands have the same functionality whichever of the main or advanced parameters are displayed in the top part. Refer to [Multi Compressor](#) for more information on these controls.

Phaser

The Phaser can produce a wide array of sonic results exceeding the conventional limits of standard phasers. Phasing is a modulation effect that sends a signal through a series of all-pass filters. Each filter alters the phase of a set frequency, and an LFO is used to modulate this phase shifting, producing a characteristic sweeping sound. When the effect signal is mixed with the original, the out of phase frequencies create notches and peaks in the frequency spectrum. The number of all-pass filters (**Stages**) determines the number of notches and peaks, and the **Feedback** control sends the effect signal back through the series of all-pass filters, increasing the resonance for an even more intense sound.

For a simple and classic guitar stomp-box style phaser, a relatively low Feedback setting should be used, with a positive polarity setting. For a sonically complex sound, use a higher number of all-pass stages. Fine-tuned coloration settings are predetermined, with each option producing varied sonic characteristics typically found in different phaser effects. The wide sonic range and potential combinations make the Phaser effect highly powerful and versatile.

The Phaser contains the following parameters and controls:

- **Stages:** Selects the number of all-pass (AP) filter stages (2, 4, 5, 6, 8). Additionally, there are two modes that offer Barber Pole phasing. In these modes, the traditional LFO modulation controls are replaced by a **Freq** control that is used to create infinite upwards-downwards motion through the frequency spectrum. The two Barber modes differ in range. The AR mode features audio-rate modulation.

- **Modes:** Selects one of five modes that determine the type of modulation and the internal routing of the phaser. The available parameters vary depending on the chosen mode.
 - **Parallel:** The LFO modulation is identical for the left and right channels while the audio inputs are still true stereo. This mode is best suited for the classic stompbox phaser sound.
 - **Wide:** The LFO modulating the flanger is identical for the left and right side, but one side is slightly offset, resulting in a wider, stereophonic sound. The modulation itself remains monophonic.
 - **90°:** The LFO phase is shifted by 90 degrees on one side, producing a bigger difference between the left and right channels. This results in a wider, more stereophonic sound.
 - **180°:** The LFO modulating the flanger is shifted by 180 degrees (inverse modulation) on one side, resulting in an even wider stereophonic sound. In Barber mode the movement is inverted between both sides.
 - **Manual:** In Manual mode, the internal LFOs are switched off and you have individual control over the frequency parameter of both channels. Applying different modulations to the left and right sides produces dramatic effects.
- **Color:** Selects one from three different settings (Neutral, Stomp, Narrow) that determine the coloring of the phaser. For classic stomp-box behavior, the **Stomp** setting is ideal. **Narrow** does not influence the spectrum around the all-pass peaks as strong as the other settings, making it suitable for darker, bass-heavy sounds. Use the **Neutral** setting to produce a neutral tone.
- **Mix:** Adjusts the amount of phasing applied. Turn the control fully left, to bypass the effect. The center position typically produces the maximum notch effect. Turned fully right, the pure phaser is heard. The best position will be dependant on the number of stages, the polarity setting, and the desired effect. The sweet spot is very often around the middle or close to fully wet.
- **FB:** Controls how much feedback is applied to the signal. The more feedback the stronger the all-pass filters will resonate. This is similar to your typical lowpass resonance filter. The more resonance, the more the frequency peaks, and gaps are modeled out of the sound spectrum. For a classic phaser sound, set the range between 30%-70%.
- **FB +/-:** Switches between Positive and Negative polarity settings, which determine whether the internal feedback is mixed in with normal or inversed polarity. This greatly influences the overall characteristics of the phaser, particularly with stage settings **2** and **4**. Negative feedback produces funky, formant-style sounds. Positive feedback produces round, bass-heavy sounds.
- **Freq:** Determines the basic operating frequency of the phaser. The LFO modulation is applied around this center frequency. In **Barber** mode, the **Freq** parameter controls the rate of the upwards/downwards movement through the frequency spectrum.
- **Rate:** Determines the Modulation Rate of the LFO. In **Barber** mode, the Rate of the modulation is controlled by the **Freq** parameter.
- **LFO Shape:** Select one of four modulation shapes (Triangle, Round, Ramp Up, Ramp Down).
- **Amount:** Sets the range of how much the LFO is animating the all-pass filters. This control is only available when an LFO is active.

Quad Chorus

Choruses are used to enrich sounds by adding spatial movement and giving them an ensemble-like quality. The Quad Chorus comes with multiple characteristics and different play modes. The Chorus is true stereo.

The Quad Chorus contains the following parameters and controls:

- **Modes:** Selects one of five modes that determine how the four delay lines are activated and modulated in different ways. The modes are based on the most successful classic chorus effects.
 - **TriVintage:** Modeled after a famous device, this mode use only three of the available four delays. It can reproduce the classic sound of a triphase chorus, but also offers additional controls, expanded ranges and stereo possibilities.
 - **Quadron:** Follows the same principles as TriVintage mode, but is optimized for a stereo signal. It can be used for subtle to over the top chorusing.
 - **Random:** This mode uses random walk generators instead of the internal LFOs. This avoids audible modulation patterns, making it ideal for subtle chorusing.
 - **Even:** Offers a special combination of two synced LFO's, spread and applied to four delay lines.
 - **Manual:** Gives you direct access to the basic core of the algorithm, in this case, the four delays. You can use this to create a subtle aural room effect or modulate it with the LFO's, envelopes, or performers. You can access the delay lines by the four controls, labeled **Time Left1, Time Left2, Time Right1, Time Right2**.
- **Flavor:** Selects one from five different settings (Neutral, Light, Controlled, Warm, Dark) that determine the coloring of the chorus. Which flavor fits best is highly dependant on what you want to achieve, but their names suggest the general character of each setting.
- **Mix:** Blends between the input signal and the effect signal, determining how much chorus is applied. Turn the control fully left to bypass the effect. The sweet spot often lies around the center position.
- **Stereo:** Adjusts the width of the stereo field. Turn left for a narrow stereo field, and turn right to widen the stereo field of the chorused signal.
- **Distance:** The time distance of the modulated delay lines to the original sound. Turn the control right for longer settings that will result in a recognizable delay effect. It can also produce interesting results for auxiliary modulation when the internal LFOs are not used. The Distance control is not available in **Manual** mode.
- **Rate:** Sets the Modulation Rate of the internal LFOs. The LFO shapes cannot be chosen, as they are an integral part of the models. The Rate control is not available in Manual mode.
- **Amount:** Sets the range of how much the LFO is animating the delay lines. The Amount control is not available in **Manual** mode.

Reverb

The Reverb offers a range of modes that mimic different room types and spaces, designed for various kinds of applications.

The Reverb contains the following parameters and controls:

- **Modes:** Selects one from seventeen different Reverb modes (Late, Large Hall, Jazz Hall, Stage, Med Synth, Fat Synth, Reflective, Rave Cellar, Small Early, Small Dense, Micron, Tight, Metolla, Wave, Woosh, Non Linear, Wanderlust), that determines the sound character and behavior of the Reverb effect.
- **Send:** Determines the amount of input signal that will be routed into the reverb engine.
- **Mix:** Blends between the input signal and the effect signal, determining how much of the reverb effect is mixed with the dry signal. Turn the control fully left to bypass the effect, or turn right to mix in the reverb.
- **Size:** Adjusts the size of the simulated room, or reverb effect. This control affects the duration of the reverb tail.
- **Color:** Adjusts the coloration of the reverb using an internal filter to subtly change the sound from dull to bright.
- **Delay:** Determines the pre-delay of the reverb effect. No delay is added when the control is turned fully left.
- **Chorus:** Applies a chorusing effect to the reverb. This can add movement and depth to the sound, producing a lively reverb that evolves over time.

Stereo Delay

The Stereo Delay offers individual time control over the left and right channels, making it an extremely powerful and versatile stereo delay effect.

The Stereo Delay contains the following parameters and controls:

- **Route:** Determines if the internal feedback is in Parallel or Cross mode. When **Parallel** is selected, the output from the left delay is fed into the left delay input and the output from the right delay is fed into the right delay input. They do not interact with each other. When **Cross** is selected, the output from the left delay is fed into the input of the right delay, and the output from the right delay is fed into the left delay input. This creates different reflection patterns that are typically longer and more complex. By default, Route is set to Parallel.
- **Color:** Selects between three different characteristics (Neutral, Warm, Hot). With a **Neutral** setting, the internal EQ filters have no resonance and there are almost no nonlinearities, making this the cleanest sounding with a neutral character. With a **Warm** setting, the internal EQ filters have some resonance, creating a warm character sound. **Hot** has strong nonlinearities and the internal EQ filters have a strong resonance that is very audible in the final sound.
- **FB:** Determines the amount Feedback applied to the signal. Applying more Feedback increases the number of echoes. Each one of these repetitions will gradually fade out as new ones are produced, with shorter delay times typically causing reflections to disappear faster than longer delay times. The Stereo Delay rescales the reflection levels so that the decay is time independent.
- **Mix:** Blends between the input signal and the effect signal. Turn the control fully left to bypass the effect, and right to mix in the delay.
- **Sync:** Selects one of two basic time manipulation modes (Sync, Free). In **Sync** mode, the fader scans through five individually assignable, synchronized times in a quantized manner. Adjust the individual dominators and denominators by clicking a number and dragging the mouse up or down. This delay's sophisticated algorithms enables you to jump from one time division to another without audio artefacts. This also applies when the host tempo is changing the master tempo of the effect. This makes it possible to modulate the faders. When **Free** is selected, the stepped fader(s) is replaced by a continuous fader, operating in a manner typical to vintage delay.
- **Mono:** When activated, **Mono** modulation is switched on. The effect remains in stereo, but the delay time is controlled by a single fader for both channels.
- **Latch:** This button enables you to recall the delay times with note-on messages received from the synth engine. This means you will only hear the change of delay times when a new note is pressed. This enables you to synchronize the delay changes to actual notes playing and is available in both **Sync** and **Free** modes.
- **Send:** Determines the amount of input signal that will be routed into the delay engine.

- **Flutter:** Moves the delay time slightly, creating a more lively effect and avoiding fixed phase relationships to the input signal. This control can be likened to a subtle chorusing.
- **Color:** Adjusts the internal filters of the delay circuitry. Turn the control left for a strong lowpass effect that becomes weaker towards the center position. At the center position the color is neutral. Turn the control right to increase the highpass filtering.

Stereo Expander

This module is the next iteration of the Dimension Expander found in the original Massive. It is cleaner, more versatile, and less CPU intensive than its predecessor. The Stereo Expander can be used to create room-style spatial effects for a wide range of mono and stereo sound sources. It has a clear, diffused character sound.

The Stereo Expander contains the following parameters and controls:

- **Amount:** Adjusts the strength of the effect.
- **Time:** Adjusts the delay time of the effect. Turning the control right increases the delay time, making the sound appear more distant.

17. Performers

The three Performers are specialized sequencers for modulation. They provide a flexible way to apply complex, rhythmical movements to parameters that usually are achieved by automation created in a host sequencer. Therefore they are key to make intricate modulations part of a Massive X sound.

They are accessed and assigned via the Navigation Bar using the tabs labeled **P1**, **P2**, and **P3**. For information about assigning the Performers to parameters, refer to [Assigning the Performers](#).

Basic and Custom editor options that enable you to quickly paint complex modulation shapes onto the Performer grid in order to form up to 12 patterns. The default Basic editor offers flexibility, while the Custom editor allows you to create a complex rhythmic grid for tailored and precise results.

The Performers can be controlled using the Remote Octave, which allows you to switch between patterns remotely using MIDI notes as key switches, or by selecting one of the 12 patterns using the mouse in the footer of Massive X. For more information about the Remote Octave, refer to [Remote Octave](#).

i This feature is not available in Massive X Player.

Performers overview

The Performers contains the following key elements and controls:

- Vertical grid tab (X-Axis):** Enables you to set the rhythmic timing for painting shapes on the grid, and contains two sets of tools: **Basic** and **Custom**. You can switch between these tools by clicking the underlined **Basic** / **Custom** label
 - Basic Tools:** The default option to define the rhythmic grid for adding modulation shapes to the Performer grid using the painting tools. Use Basic mode to define the time signature and rhythmic resolution of the grid from quarter notes down to 32nd note divisions.
 - Custom Tools :** Used to create custom time signatures with up to eight different sections. Use the Custom Grid to create your own complex time signatures. When using Custom mode, set the number of beats per bar, a beat length, and subdivisions.

You can safely switch between the Basic and Custom grid without losing your modulation pattern. Switching between them only changes the underlying grid, not the pattern.

2. **Horizontal grid tab (Y-Axis):** Provides options to set the number of steps for parameter values (quantization) in the Performers' Horizontal grid. By default, the number of steps is set to 24 (bipolar -24 to +24, unipolar 0 - +24). The **Snap to Grid** option ensures the grid value is adhered to even when making fine adjustments by holding the right mouse button and dragging.

An important thing to bear in mind when using the grids is that they are not separate, they simply work together to provide flexibility when adding modulation.

3. **Overlay grid tab:** When the overlay is switched on, the overlay placement and width can be adjusted using the three handles that appear in the Select zone. The number of divisions is set by dragging up or down over the **Overlay Divisions** value. To the left, the overlay also features stretch controls that can be used like the ones found next to the painting tools. The difference is that the grid itself is stretched (not the position of the modulation points of a multi-selection). This makes it easy to use the overlay as a guide for creating modulation sections that speed up or slow down. The overlay can also be used to create wider grid values than quarters or odd divisions over any irregular timing.
4. **Overlay On/Off switch:** Displays or hides the grid overlay.
5. **Painting tools:** The selected brush defines the modulation shape that is painted on the grid. The length of a shape is determined by the length of the grid division. For more information on the painting tools, inserting and editing modulation, refer to [Editing Modulation](#), and [Painting Modulation Painting Tools](#).
6. **Stretch tools:** Select multiple points in the Select zone and use these tools to stretch or compress the modulation curves in the pattern by dragging upwards or downwards. The upper tool stretches or compresses points to the left or right. The lower tool stretches or compresses points inwards or outwards.
7. **Range switch:** Sets the range of the Performer to bipolar or unipolar.
8. **Initialize:** Click to clear all modulation data and reset the grid to bipolar or unipolar.
9. **Rate:** Set the speed of the Performer based on the tempo of your host; at the center position, the speed is the same as your host. At the far-left position, the rate is at an eighth of the host, and at the far-right, it is eight times that of the host.
10. **Level:** Sets the output level of Performer modulation. When turned to the left position, the output is at zero, when turned to the right position, it's at 100%.
11. **Start/End markers:** You can drag the marker handles to define the start and endpoints of the section of the modulation you want to play. The marked section will play according to the playback mode selected in the Performer Grid Overview. For more information on selecting playback modes in the Performer Grid Overview, refer to [Remote Octave overview](#).

Double click the Start/End marker bar to adjust the playback area to the visible section in the editor, as set by the Zoom bar.

12. **Select zone:** Click and drag in this area to select multiple modulation points. For more information on editing modulation, refer to [Editing modulation](#).
13. **Grid:** The area where modulation is painted onto the flexible grid using the painting tools.
14. **Segment Edit zone :** Use this area to edit single or multi-selected segments. Right-click and drag to fine-tune segments on the grid without them snapping to the quantize value. Double-click on a segment or multi-selection to delete it.
15. **Zoom bar:** Click and drag the handles to zoom in and out of the Performer timeline. Double-click the Zoom bar to zoom into the first bar of the grid.

Assigning the Performers

Before the effect of the Performer's modulation pattern can be heard, it must first be assigned to a parameter. The process for assigning each Performer is the same, and a Performer can be assigned to multiple parameters at once.

To assign a Performer to a parameter:

1. Drag the arrow icon of Performer 1 (**P1**) to, for example, the first modulation slot of the Wavetable Position. When the outline of the modulation destination is highlighted, release the mouse button.

- Click and drag the modulation slot upwards to increase the modulation amount applied to the Wavetable Position from the Performer.

- Repeat this process to assign the Performer to more parameters or to assign Performers (**P2** and **P3**) to parameters.

You can double-click the modulation slot to set the maximum modulation amount or reset it to zero.

Vertical grid

The Vertical grid (X-Axis) provides the time division and note value options to set the rhythmic timing for painting shapes on the grid. It also contains two sets of tools for painting on the grid. These are named **Basic** and **Custom**:

Basic tools

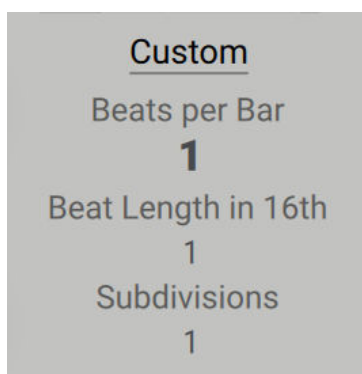

The **Basic** tools are the default option for painting modulation shapes with the shape brushes onto the Performer grid. Use Basic mode to define the time signature and rhythmic resolution of the grid from quarter notes down to 32nd note divisions.

- **Painting tools:** The selected brush defines the modulation shape that is painted on the grid. The length of a shape is determined by the length of the grid division. For more information on the painting tools, inserting and editing modulation, refer to [Painting Tools](#), [Painting Modulation](#), and [Editing Modulation](#).
- **Stretch tools:** Select multiple points in the Select zone and use these tools to stretch or compress the modulation curves in the pattern by dragging upwards or downwards. The upper tool stretches or compresses points to the left or right. The lower tool stretches or compresses points inwards or outwards.

Custom tools

The **Custom** tools are used to create custom time signatures with up to eight different sections. Use the Custom Grid to create your own complex time signatures. When using Custom mode, you can set the number of beats per bar, a beat length, and subdivision.

i You can safely switch between the Basic and Custom tools without losing your modulation pattern. Switching between them only changes the underlying grid, not the pattern.

Painting tools

The painting tools enable you to paint modulation shapes onto the rhythmic grid.

Here is an overview of the painting tools:

1. **Edit:** Use to add modulation points to the Performer grid. The points are connected as straight lines to neighboring points.
2. **Line:** Creates lines from the start to the endpoint of a grid segment.
3. **Step:** Creates static values that extend to the end of a grid segment.
4. **Ramp A:** This tool creates descending ramps.
5. **Ramp B:** This tool creates ascending ramps.
6. **Triangle:** Creates triangle shapes.
7. **Sine:** Creates sine shapes.

Painting modulation

Select one of the shape brushes to start painting modulation on the grid. As you use the brushes to create shapes, they will snap to the selected time signature division and note value. For more information on selecting time signatures and note values, refer to [Performers overview](#).

To draw modulation onto the grid:

1. Select a time signature and grid note value.

2. Select a paint tool.

3. Click and drag the mouse across the grid to paint modulation.

4. Move the mouse up and down while painting to change the MIDI data amount.

i The Performer only starts playing when it is assigned to a parameter of an active module. For more information on assigning Performers to parameters, refer to [Assigning the Performers](#).

Editing modulation

This section provides an overview of the features available for editing modulation in the Performer grid.

Selecting modulation

To select modulation points:

- In the Selection Zone, drag across any selection of modulation points to highlight them. For more information on the Selection Zone, refer to [Performers overview](#).

Deleting modulation

You can delete individual or multiple modulation points.

To delete a single modulation point:

- ▶ Double-click the modulation point.

To delete multiple modulation points:

- ▶ In the Select zone, select the points that you want to delete, then double-click in the Segment Edit zone.

Alternatively, you can select a modulation point and drag left or right. Any existing points from the selected modulation point to the target location are deleted as the mouse is moved.

To delete all modulation within a Performer:

- ▶ Click the **Initialize** button and select **Bipolar** or **Unipolar** or double-click the pattern in the Remote Octave overview to reset the grid.

To delete all three modulation patterns for all three Performers:

- ▶ Double-click in the lower grid area of the Remote Octave overview.

For more information on the Remote Octave, refer to [Performers overview](#).

Moving modulation

You can move modulation points in values quantized or unquantized to the grid value.

To move a selection of modulation points in steps quantized to the grid:

- ▶ In the Select zone, select the points that you want to move, then in the Segment Edit zone, drag them horizontally.

To fine-tune a selection of modulation points unquantized to the grid:

- ▶ In the Select zone, select the points that you want to move, then in the Edit zone, drag horizontally holding the right mouse button.

For more information on the Select zone and Segment Edit zone, refer to [Performers overview](#).

Bending a modulation curve

- ▶ Place the mouse over an existing modulation curve on the grid, then click and drag upwards or downwards.

18. Remote Octave

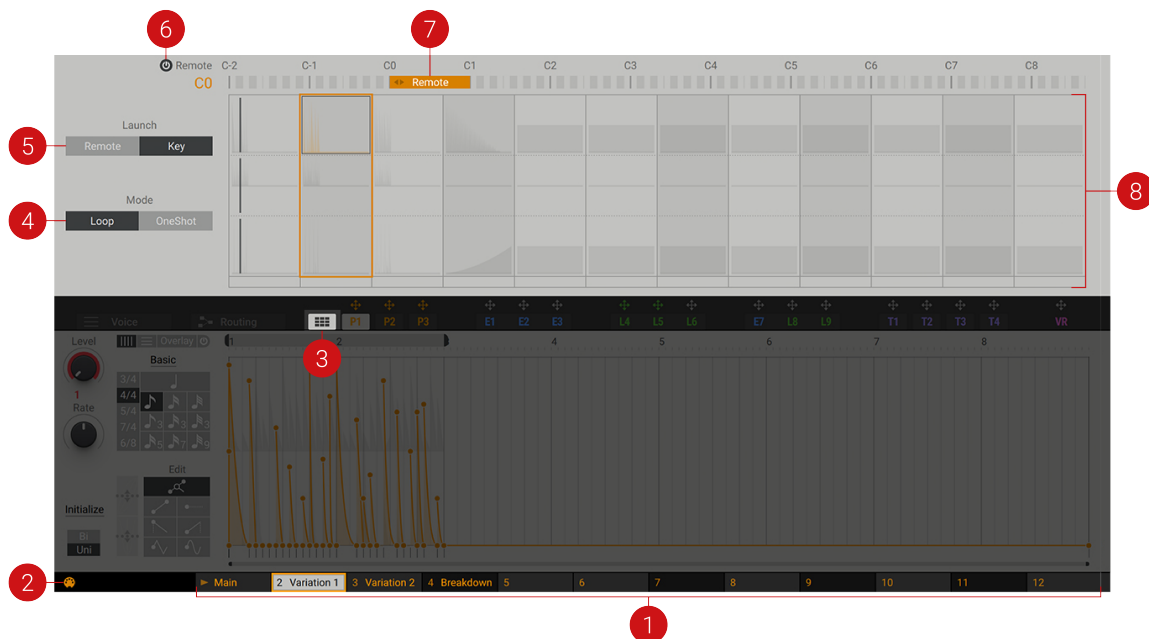

The Remote Octave provides a special key zone with access to 12 optional variations of the Performers **P1**, **P2**, **P3**. These alternative sets can be switched remotely using MIDI notes as key switches or by selecting one of the 12 patterns using the mouse in the footer of Massive X. This allows drastic changes to be performed or programmed by triggering remote key switches from your host. The Remote Octave acts like a remote control on your keyboard controller that allows you to select different Performer modulation patterns. This can be used in a performance to change modulations on the fly for variation, or for precise control when programming remote sequences in your favorite host sequencer.

In the Performer Grid view, a simultaneous overview of all three Performers is available, making it easy to copy, swap, and delete the 12 patterns from each Performer. You can also set up how patterns are triggered and how they can be changed with key switches using the Remote Octave. For more information about the Performers, refer to [Performers](#).

i This feature is not available in Massive X Player.

Remote Octave overview

The Remote Octave contains the following elements and controls:

1. **Remote Octave Keys:** The bottom area holds the 12 keys of the Remote Octave. This area displays information about the activity states and is used to manually change the active patterns of all Performers using the mouse. The patterns here directly correlate to each note of the chromatic scale within the Remote Key Zone.

Here's an overview of the Remote Octave key states:

- A Play icon next to the name of a pattern indicates the Performer pattern currently playing.

- An orange outline highlights which pattern will play when the next launch trigger is received. This signal can be triggered by a change of the Remote Octave (for example, switching via the mouse in the footer or MIDI note in the Remote Octave zone) or by a MIDI note, refer to (5) for more information.

- An orange fill indicates a pattern that is currently open in the Editor and playing. Selecting a key with a right-click will open the associated pattern to be edited while another pattern is playing.

- A gray fill indicates the pattern currently being edited but not playing. It is possible to have one pattern playing while editing another, to do this, right-click a pattern other than the one playing.

2. **Remote MIDI control:** This button mutes incoming MIDI notes to the Remote Octave key zone (defined on the Performer Grid view. This function can be used, for example, to deactivate remote switching from a host sequencer while editing and listening to the modulation effect of a Performer pattern.
3. **Performer Grid view:** The Grid option button becomes visible when the Performer editor is selected and shown in the lower area of Massive X. It opens the Grid view that holds playback options for the Performer and an overview of all Performer patterns.
4. **Trigger modes:** This selector switches between **Loop** and **OneShot** modes.
 - **Loop:** The section within the Start /End Markers will repeat.
 - **OneShot:** The section within the Loop Markers will play once only.
5. **Performer Launch options:** This selector switches between the Performer Launch options. The Performer options are globally applied to all three Performers.
 - **Remote:** Starts or retriggers a modulation pattern directly when a pattern is changed or reselected. Use the Remote option when you want to sequence modulation pattern changes with your host sequencer.
 - **Key:** Starts or retriggers a pattern when a note is played. Use Key when you want to restart the modulation pattern every time a note is played.
6. **Remote Power button:** This button activates or deactivates control of Remote Octave key switches via MIDI. This bypasses the key zone filtering so that the whole keyboard range can be used to play notes.
7. **Remote Key Zone:** The key zone for MIDI note control of the Remote Octave can be shifted up and down in octaves by dragging the Remote handle left and right.

8. Performer Grid Overview This is used to select a modulation pattern for editing. It features the **P1** at the top, **P2** in the center row and **P3** at the bottom row. The column holding the patterns currently playing is highlighted with an orange outline. The pattern visible in the editor has a black outline. There is also a playback cursor as seen in the Performer editor. The 12 pattern variations are placed next to each other on the same row. The Grid offers an overview of all modulation patterns and provides a convenient way to copy and swap pattern sets and individual patterns.

- To copy a pattern, drag and drop a pattern onto a different slot.
- To swap the patterns, right-click and drag and drop between two slots.

19. Modulators

Modulation is a key component of all forms of synthesis. It is the way in which you shape a signal and the tool with which to breath life and movement into a sound. Massive X provides nine modulation sources in the form of Modulators, which can be used to control various parameters across the synth. Modulator 1 is a dedicated **Amp-Envelope**, hard-wired to control the Amplifier level. Each of the remaining eight Modulators can be assigned to any of the four modulation sources: **Modulation Envelope**, **Exciter Envelope**, **Switcher LFO**, and **Random LFO**. On a basic level, Modulators can be used to apply LFOs or envelopes to create simple contours or add motion to a sound. However, through an extensive network of modulation routing possibilities, as well as the specific controls of the Modulators themselves, more intricate arrangements can be constructed.

 This feature is not available in Massive X Player.

The Modulators are accessed and assigned via the Navigation Bar using the tabs labeled e.g. **E1**, **E2**, **E3** for envelopes and **L1**, **L2**, **L3** for LFOs. For information on how to assign the Modulators to parameters, refer to [Assigning modulation](#).

The flexible and comprehensive range of modulation sources and routing possibilities provide considerable power for sound design. When properly exploited, the Modulators can go beyond your basic modulation needs, facilitating more advanced applications, like physical modeling, velocity-sensitive envelope shaping, multi-stage envelopes for complex shaping and so much more.

Envelopes

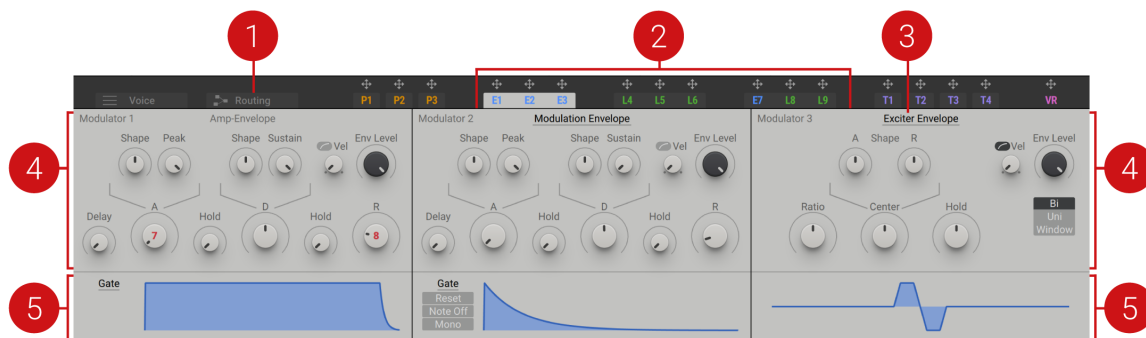

Envelopes are one of the most common and powerful tools for contouring your synth sound. In more typical use cases, envelopes control the loudness of an amplifier, shape the tone and color of a filter, or adjust the pitch of a signal. They can also be used for more creative objectives, like applying modulation to the speed of a sequence, the delay time of a stereo effect, or the rate of another Modulator.

LFOs

While envelopes create motion by defining the contour over a set of time and level based stages, LFOs typically have a fixed wave shape, useful for producing cyclical, predictable rhythmic modulation. LFOs (low frequency oscillators) produce a signal below the human range of hearing. As the signal cannot be heard, it is ideal for producing movement and animation, adding a sense of motion and depth to a sound. Modulation effects can become a defining character of a sound, for example, vibrato when an LFO is applied to the pitch of an oscillator, or tremolo when applied to an amplifier. Slow LFOs allow for subtle, elongate changes over time, while higher frequency rates can be used as a source for frequency modulation, amplitude modulation, and other types of audio-rate modulation.

Modulators overview

The Modulators feature the following key elements and controls:

1. **Routing tab:** Two Modulation modules can be accessed via the Routing page, allowing you to use modulation sources as generators in the signal path. For more information, refer to [Modulation modules](#).
2. **Modulators:** The Modulator type and number of the assigned to each slot is displayed here. Envelopes are represented with a blue **E** and LFOs are represented with a green **L**. Click on a Modulator to display the corresponding parameters. When a Modulator is selected, its tab is highlighted as in the image above. Click on the arrow icon above the Modulator to assign it to a modulation slot. For more information, refer to [Assigning modulation](#).
3. **Modulator menu:** Select from four modulation sources (**Modulation Envelope**, **Exciter Envelope**, **Switcher LFO**, **Random LFO**).
4. **Controls:** The knobs and menus in this section are used to edit the shape and behavior of the Modulators.
5. **Display:** A visual representation of the current shape of the Envelope is displayed here, as determined by the trigger and knob settings. Moving the controls will show how each parameter influences the shape of the Envelope. Additional menus and settings relating to the behavior of the Modulator are also found here.

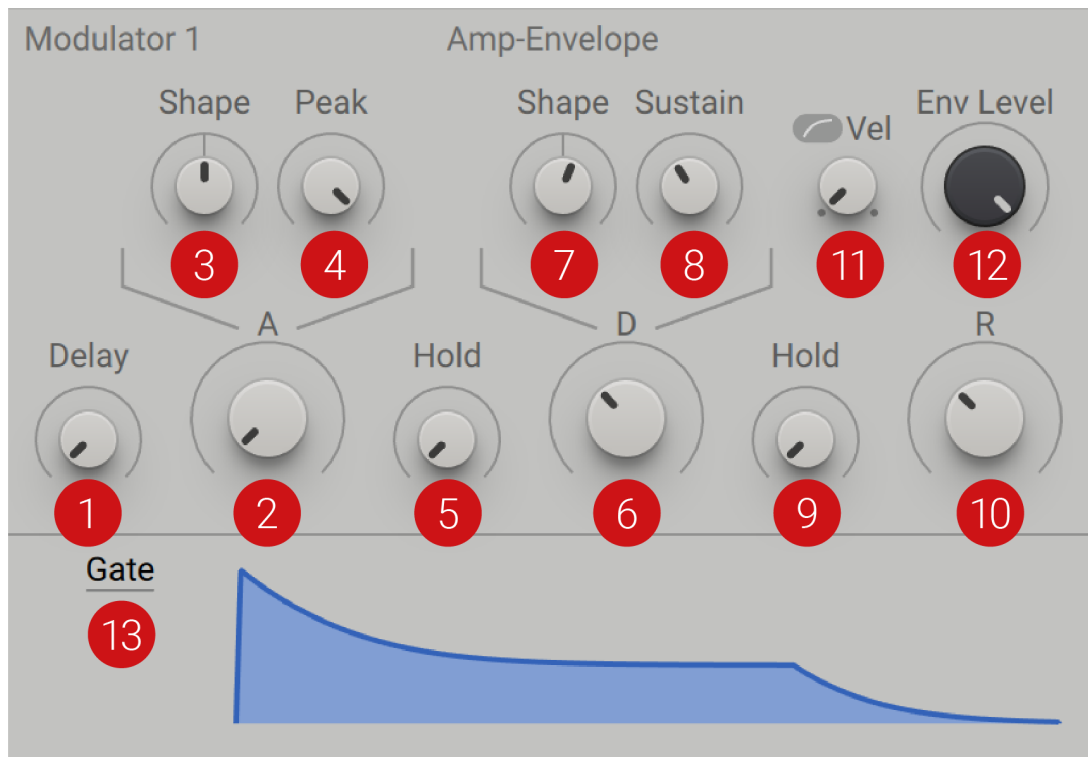

Amp Envelope

The Amp Envelope is used to control the response and shape of the Amplifier. Hardwired to the Amplifier, it offers individual scaleable curve controls over the **Attack** and **Release** stages, as well as **Delay** and **Hold** stages that provide additional control over the Amplifier's articulation.

In relation to human perception of amplification, small changes at low amplitude typically have a distinct and pronounced effect, while small changes made at higher volumes produce a less obvious result. Exponential shapes, as found on the **Shape** controls are especially effective for controlling the amplitude as they work to balance out the logarithmic shape of the amplifier, producing a smoother and more continuous change in volume.

The **Trigger** modes allow you to adapt to the way the Amplifier receives MIDI triggers. **Gate** mode is particularly useful when playing with a keyboard, as it provides a way to control the sound depending on the duration and intensity at which a key is pressed and held. For more information about the Amplifier, refer to [Amplifier](#).

The Amp Envelope contains the following parameters and controls:

1. **Delay:** Applies a delay to the onset of the envelope. When turned fully left, no delay time is applied and the envelope starts at the **Attack** stage. Turning the knob right increases the delay time.
2. **Attack (A):** Adjusts the time the envelope takes to reach the peak level. Turned fully left, the envelope will start immediately. As you turn the control right, the **Attack** becomes longer, and your sound will have a smoother start.
3. **Attack Shape:** Changes the curve of the **Attack** stage of the envelope. Turning the knob left to right fades the curve from exponential to linear to logarithmic.
4. **Attack Peak:** Defines the maximum level that can be reached. The scope of this control is dependant on the **Velocity** setting.
5. **Hold:** Determines the fixed amount of time that the peak level of the envelope is held between the end of the **Attack** stage and the start of the **Decay** stage.
6. **Decay (D):** Adjusts the amount of time it takes to fall from the attack's maximum **Peak** level to the level defined by the **Sustain** control. Turned fully left, the **Decay** stage will start immediately, and turning the knob right increases the Decay time.
7. **Decay Shape:** Changes the curve of the **Decay** stage of the envelope. Turning the knob left to right fades the curve from exponential to linear, and then to logarithmic.
8. **Decay Sustain:** Sets the amplitude of the **Sustain** stage.
9. **Hold:** Determines the fixed amount of time that the peak level of the envelope is held between the end of the **Sustain** stage and the start of the **Release** stage.
10. **Release (R):** Defines the amount of time it will take for the envelope to fall from the set **Sustain** level and fade to zero.
11. **Env Level:** Defines the overall level of the envelope.

12. **Velocity**: Controls the influence of the incoming MIDI note's velocity on the overall amplitude of the envelope. When turned fully left, the envelope amplitude is not influenced by the velocity of the incoming notes. When the fader is turned fully right, the overall envelope amplitude is directly proportional to the velocity of the incoming notes. The **Velocity button** changes the slope of the **Velocity** control from linear to logarithmic, when activated.
13. **Trigger**: Selects one of three settings (Gate, OneShot, LoopGate), that determine the envelope's response to incoming MIDI notes.
 - With **Gate** is selected, the envelope is started and read out until its end when triggered. If the key is released before the **Sustain** stage of the envelope, it will immediately jump to the **Release** stage.
 - With **OneShot** selected, the envelope is read to end, even if the key is released before the **Sustain** stage.
 - **LoopGate** creates a loop between the **Attack** and **Decay** stages.
 - **Loop** creates a loop from the entirety of the envelope, including the **Release** stage.
14. **Display**: Provides a visual representation of the envelope shape, based on how the knobs and menus are set. Move the controls described above to see how each parameter influences the shape of the envelope.

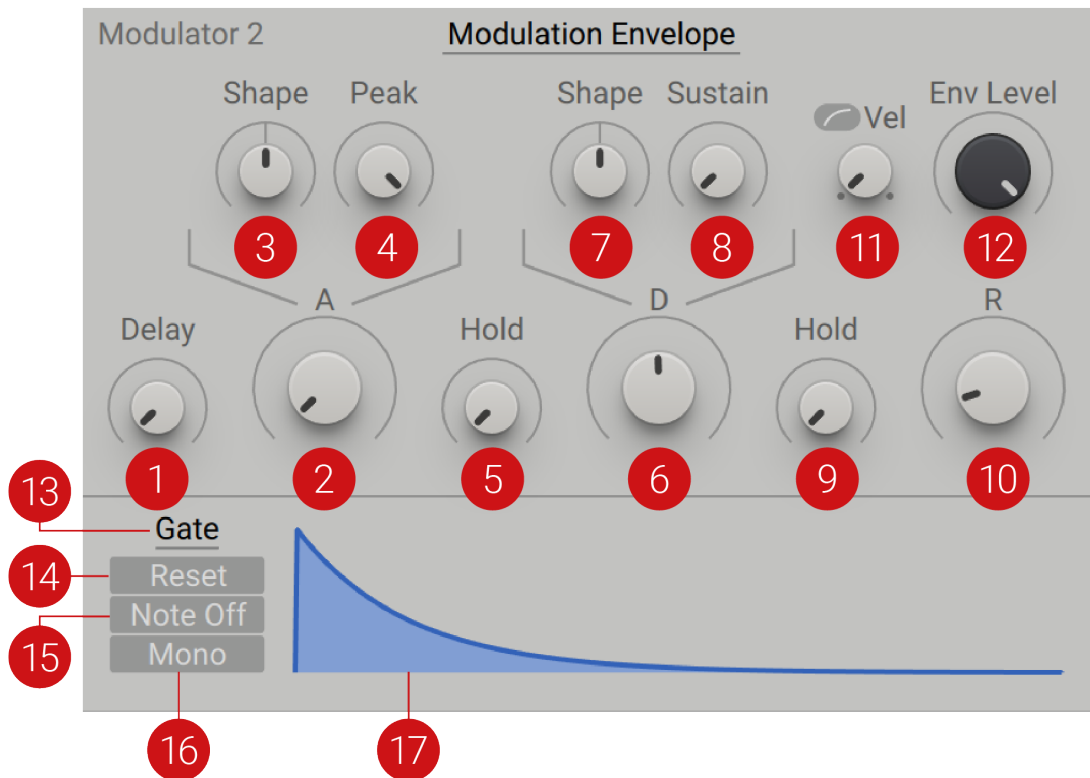

Modulation Envelope

The Modulation envelope in Massive X offers a highly flexible and precise way of shaping your signal. Through comprehensive routing options, this envelope can be used to control virtually any aspect of the signal.

Alongside the standard **Attack**, **Decay**, **Sustain** and **Release** parameters, one **Delay** stage and two **Hold** stages provide additional control over the shape and contour of the envelope, enabling you to create sounds that seemingly have multiple sustain stages. The **Delay** control is typically used to delay the start of modulation, or to delay the impact of a modulation source. It occurs before the start of the envelope and can be particularly useful in sound design, for example, creating a measured time between the onset of the Amplifier envelope and a Filter envelope. By delaying the Filter envelope, a double attack-style effect is produced, opening a world of intricate sound design possibilities.

Attack Shape and **Decay Shape** allow you to determine the slope of the envelope when rising and falling. This allows for more precise sculpting and contouring, as different shapes are more suitable for different musical uses. Linear shapes set a direct path from one stage to the next, while exponential curves are commonly used to create pitch sweeps, as they create a more effective continuous sweep than a linear or logarithmic envelope.

The Modulation Envelope contains the following parameters and controls:

1. **Delay:** Applies a delay to the onset of the envelope. When turned fully left, no delay time is applied and the envelope starts at the **Attack** stage. Turning the knob right increases the delay time.
2. **Attack (A):** Adjusts the time the envelope takes to reach the peak level. Turned fully left, the envelope will start immediately. As you turn the control right, the **Attack** becomes longer, and your sound will have a smoother start.
3. **Attack Shape:** Changes the curve of the **Attack** stage of the envelope. Turning the knob left to right fades the curve from exponential to linear, and then to logarithmic.
4. **Attack Peak:** Defines the maximum level that can be reached. The scope of this control is dependant on the **Velocity** setting.
5. **Hold:** Determines the fixed amount of time that the peak level of the envelope is held between the end of the **Attack** stage and the start of the **Decay** stage.
6. **Decay (D):** Adjusts the amount of time it takes to fall from the attack's maximum **Peak** level to the level defined by the **Sustain** control. Turned fully left, the Decay stage will start immediately, and turning the knob right increases the Decay time.
7. **Decay Shape:** Changes the curve of the **Decay** stage of the envelope. Turning the knob left to right fades the curve from exponential to linear to logarithmic.
8. **Decay Sustain:** Sets the amplitude of the **Sustain** stage.
9. **Hold:** Determines the fixed amount of time that the peak level of the envelope is held between the end of the **Sustain** stage and the start of the **Release** stage.
10. **Release (R):** Defines the amount of time it will take for the envelope to fall from the set **Sustain** level and fade to zero.
11. **Env Level:** Defines the overall level of the envelope.

12. **Velocity**: Controls the influence of the incoming MIDI note's velocity on the overall amplitude of the envelope. When turned fully left, the envelope amplitude is not influenced by the incoming note's velocity. When the fader is turned fully right, the overall envelope amplitude is directly proportional to the incoming note's velocity. The **Velocity button** changes the slope of the **Velocity** control from linear to logarithmic, when activated.
13. **Trigger**: Selects one of four settings (Gate, OneShot, LoopGate, Loop), that determine the envelope's response to incoming MIDI notes.
 - When **Gate** is selected, the envelope starts and is read out until its end. If the key is released before the **Sustain** stage of the envelope, it will immediately jump to the **Release** stage.
 - With **OneShot** selected, the envelope is read to end, even if the key is released before the **Sustain** stage.
 - **LoopGate** creates a loop between the **Attack** and **Decay** stages.
 - **Loop** creates a loop from the entirety of the envelope, including the **Release** stage.
14. **Reset**: When active, the envelope will restart each time a note is triggered.
15. **Note Off**: When active, the envelope is triggered with the note-off stage, for example when a key is released.
16. **Mono**: When activated, all incoming notes receive the same envelope shape, regardless of pitch.
17. **Display**: Provides a visual representation of the envelope shape, based on how the knobs and menus are set. Move the controls described above to see how each parameter influences the shape of the envelope.

Exciter Envelope

The Exciter envelope is a particularly fast envelope that has been specifically designed to trigger the Comb filter, producing a resonator in physical modelling. It also effective for creating percussive sounds, with its quick attack and short release times.

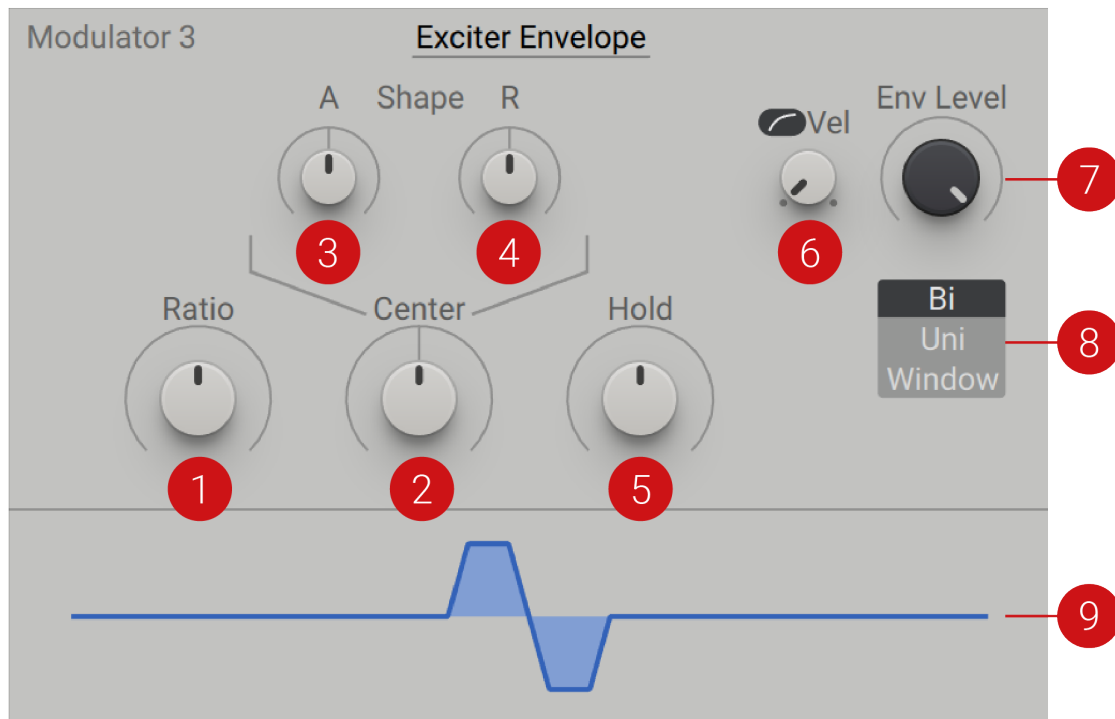

The Exciter is unlike a standard ADSR based, multi-stage envelope generator. It is an Attack-Release envelope with short times, functioning in a single cycle, with a defined centre point and **Hold** stage that maintains the peak level from **Attack** to **Release** stages.

To use this envelope as an exciter for the Comb filter, it must be assigned to one of the Modulation Sources via the Routing page, routed to the Comb filter and then the filter routed to the output. This enables you to set the Comb filter into oscillation and create tones from the **Feedback**. A low **Ratio** setting produces the short envelope burst needed to create sound from the filter. For more information, refer to [Comb](#).

You can also use the Exciter envelope to briefly trigger self-oscillation of resonant filters at high **Res** settings. This so-called filter pinging produces a damped sine wave that can be played via MIDI by using key tracking (**KTR**). The **SVF** filter types are especially suitable for this purpose.

The Exciter Envelope contains the following parameters and controls:

1. **Ratio:** Controls the length of the envelope. Turning the knob right, increases the value, resulting in a longer envelope.
2. **Center:** Tilts the envelope towards the **Attack** stage when turned left, or towards the **Release** stage when turned right.
3. **Attack Shape:** Changes the curve of the attack (**A**) stage of the envelope from parabolic to logarithmic.
4. **Release Shape:** Changes the curve of the release (**R**) stage of the envelope from parabolic to logarithmic.
5. **Hold:** Increases the width of the peak stage of the envelope, determining how long the level of this stage will be held.
6. **Velocity:** Controls the influence of the incoming MIDI note's velocity on the overall amplitude of the envelope. When turned fully left, the envelope amplitude is not influenced by the velocity of the incoming notes. When the fader is turned fully right, the overall envelope amplitude is directly proportional to the velocity of the incoming notes. The **Velocity button** changes the slope of the **Velocity** control from linear to logarithmic, when activated.
7. **Env Level:** Defines the overall level of the envelope.
8. **Polarity:** Selects one of three settings (Bi, Uni, Window) that determine the direction of modulation.
 - When **Bi** is selected, the modulation is bidirectional.
 - With **Uni** selected, the modulation is unidirectional and moves only in one direction.
 - When **Window** is selected, the envelope is unidirectional and mirrored at the center. This removes the independent controls for attack and release, and offers only one shape control as the stages are now identical.
9. **Display:** Provides a visual representation of the envelope shape, based on how the knobs and menus are set. Move the controls described above to see how each parameter influences the shape of the envelope.

Switcher LFO

The Switcher LFO offers a suite of LFO types, optimized for different use cases. The LFO is made up of the Rate, Shape, and Amp sections, running from left to right. The Rate section determines the speed and the play mode of the LFO. Depending on the mode selected, the **Rate** knob will change its appearance and functionality. **Osc** mode, provides an extremely fast modulation option that can be used in sync with the pitch of the Wavetable oscillators. The Shape section offers 16 different waveform shapes, from the typical Sine, Triangle, Saw and Square, to Ramp, Random, Spike and more.

Assigning a modulation source to the **Shape** selector allows you to scan through the different LFO shapes, creating some dramatic sonic effects. The **Fall/Rise** control in the Amp section can be used to determine the fade in and fade out of the LFO. The envelope is not velocity sensitive, and always restarts each time a MIDI gate is received. This can be particularly useful in musical applications, for example, when using the LFO for pitch vibrato, it enables you to fade in the vibrato slowly. The flexible shapes allow you to customise your LFO to tailor very specific modulation tasks.

The Play modes determine whether the LFO loops continuously or plays through one cycle only, and how the LFO cycle resets in response to incoming MIDI triggers. In addition to standard Gate and Restart behavior, **Loop REL** mode can be used to create interesting release effects.

The Switcher LFO contains the following parameters and controls:

1. **Rate Mode:** Selects one of three modes (Sync, Free, OSC), which determine the rate in which the LFO repeats its cycles.
 - In **Sync** mode, the LFO is synchronized to the host tempo. It provides a slider with five positions, each of which can be programmed to your desired time division. Editing the numerator and denominator separately allows you to produce specific time divisions, and also facilitates more esoteric ones. **Sync** mode organizes the denominator values in a non-linear manner, to provide quick access to the most common values. Standard values **/4**, **/8**, **/16**, **/32** are then followed by triplets **/12** (8-note triplets), **/24** (16-note triplets), **/48** (32-note triplets), and so on, until 99. The change of **Rate** happens as soon as the slider hits a new position, with no fading in between.
 - In **Free** mode, the **Rate** is absolute and independent from the host tempo. The slider subdivisions are replaced with a continuous knob to control the speed of the LFO. The range, in Hz, extends from very slow to very fast rates. The knob is scaled in this respect, giving finer control in the middle ranges. The overall rate range is 0.004 Hz to approximately 60 Hz. Centre position is around 5.3 Hz, which is ideal for pitch vibrato.
 - In **Osc** mode, the LFO operates at audio rate, becoming an additional keytracking oscillator. The values generated by the **Rate** control are linked to incoming MIDI notes, turning **Rate** into a control for transposition, ranging from zero when turned fully right, down to -96 semitones lower than the note pitch.
2. **Latch Rate:** When activated, changes to the **Rate** (via direct control or modulation) are latched until the next note is received.
3. **Waveform Selector:** Selects one of sixteen waveforms for the LFO. The new shape is updated with each cycle, providing a synchronized switch when heavily modulated.
4. **Latch Shape:** When activated, changes to the **Shape** (via direct control or modulation) are latched until the next note is received.
5. **LFO Level:** Amplifies the output of the LFO. Turning the knob right increases the amplification level.
6. **Polarity:** Selects from three Polarity settings (Bi, Uni, Uni Z) that determine how the envelope in the Amp section behaves.
 - When **Bi** (Bipolar) is selected, the output range of the LFO is -100% to +100%. The waveform always starts at 0%, independent of which shape is selected.
 - **Uni** (UniPolar) offers a range of 0 to 100%. The waveform will always start at 50%, independent of the selected shape.
 - **Uni Z** (UniPolar Zero) also has a range of 0 to 100% . The differences between **Uni** and **Uni Z** can only be heard when the oscillator is restarted with a new note trigger. The **Polarity** setting is reflected in the modulation.
7. **Delay:** Applies a delay to the onset of the LFO. When turned fully left, no delay time is applied and the LFO starts immediately. Turning the knob right increases the delay time.
8. **Fall/Rise:** Adjusts the way the LFO fades in or out. At centre position the LFO has infinite falling time, working as though it is always on. Turning the knob right produces a short rising ramp that becomes longer as it is turned fully right. Turning the knob left creates a very small decay fall time, which extends to a very long falling time as the control is turned fully left. The display, located below the **Fall/Rise** knob, provides a visual representation of the shape of the fades.
9. **Mono:** When deactivated, the LFO is polyphonic. Each incoming note receives its own LFO. When activated, the LFO is monophonic and all incoming notes receive the same LFO, regardless of pitch.

10. **Midi**: Switches between Midi and Remote mode for resetting and latching the LFOs. When **Midi** is selected the LFO resets and latches based on incoming MIDI note events. If **Remote** is selected the LFO resets and latches when you change key switches in the Remote Octave.
11. **Play Mode**: Selects from six settings (Loop, Loop RST, Loop GTE, Loop REL, 1shot, 1shot REL), that determine the general behavior of the LFO.
 - **Loop** is the most classic setting, with the LFO running in an infinite loop, regardless of whether notes are being played or not.
 - **Loop RST** (Loop Restart) also runs in an infinite loop, but will immediately jump to a given phase if a MIDI trigger is received from Zone or Remote.
 - **Loop GTE** (Loop Gate) follows the same behavior as Loop Restart, but cuts the LFO as soon as the note is released.
 - **Loop REL** (Loop Release) deactivates the LFO as soon as note is received. When the note is released, the LFO resets and the modulation is in effect. In this mode, it is important to set a long release time on the Amp envelope, or the effect will not be heard.
 - When **1shot** (One Shot) is selected, only one cycle of the LFO will be played. Note on will always restart the LFO and go to zero after the cycle, regardless of the LFO value or polarity setting. This ensures predictable results, regardless of the LFO waveform.
 - **1shot REL** (One Shot Release) follows the same principles as **1shot** mode, but creates a cycle when the note is released. In this mode it is also important to set a long **Release** time on the Amp envelope, or the effect will not be heard.

When in **Sync** mode, try modulating the **Rate** with another Switcher LFO. While sweeping through the positions on the slide, experiment in programming subtle variations in time divisions.

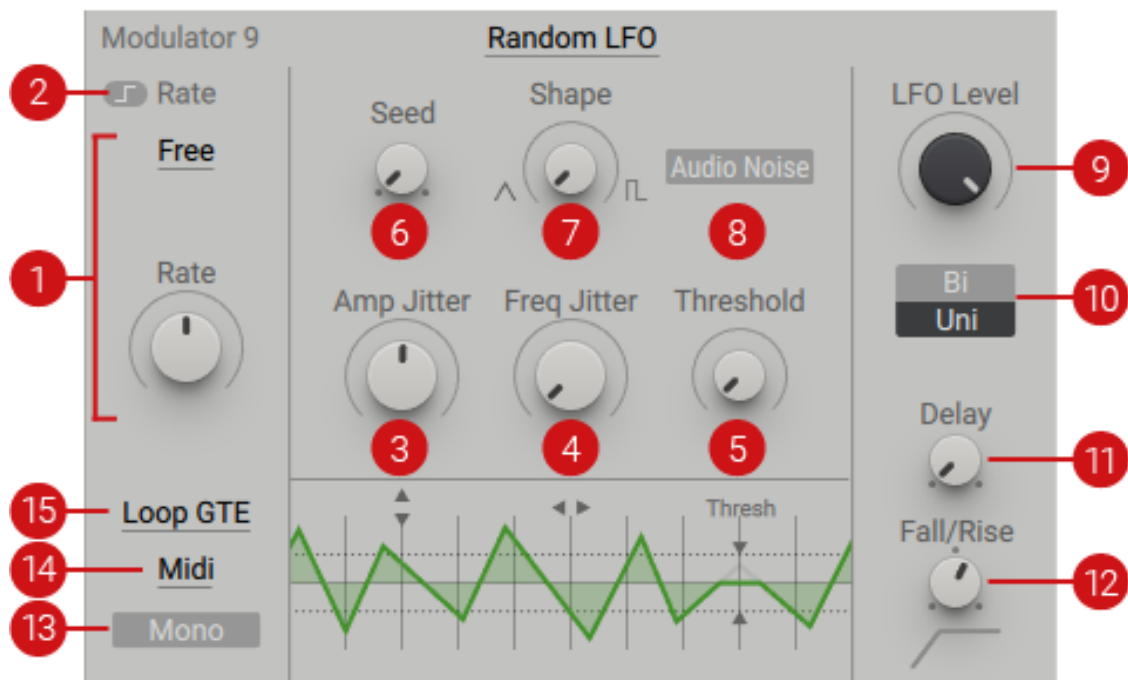

Random LFO

Adding randomness to your signal can inject human-like character to an otherwise highly controlled sound. This naturalistic quality is grounded in chance, probability and human error; the essence of what distinguishes a drummer from a drum machine. The Random LFO is a specialized LFO that generates different kinds of controllable variable random numbers, and provides controls to alter the type, range and amount of randomness applied.

The Random LFO can also be used as a generator by activating the **Audio Noise** button. Assigning the LFO to a Modulation source via the Routing page enables you to use the LFO as a noise source in the audio signal path. For more information on using Modulators as generators, refer to [Modulation modules](#).

The Amp Jitter can be used to produce a precise amount of random values. Mixing between the two extremes, particularly with fast **Rate** settings, has a significant impact on the color of the noise. The independent controls can produce a wide range of noises and random modulations.

The Random LFO contains the following parameters and controls:

1. **Rate mode:** Selects one of three modes (Sync, Free, OSC), which determine the rate in which the LFO repeats its cycles.
 - In **Sync** mode, the LFO is synchronized to the host tempo. A slider offers five positions, each of which can be programmed to your desired time division. Editing the numerator and denominator separately allows you to produce specific time divisions, and also facilitates more esoteric ones. **Sync** mode organizes the denominator values in a non-linear manner, to provide quick access to the most common values. Standard values **/4**, **/8**, **/16**, **/32** are then followed by triplets **/12** (8-note triplets), **/24** (16-note triplets), **/48** (32-note triplets), and so on, until 99. The change of **Rate** happens as soon as the slider hits a new position, with no fading in between.
 - In **Free** mode, the **Rate** is absolute and independent from the host tempo. The slider subdivision are replaced with a continuous knob to control the speed of the LFO. The range, in Hz, extends from very slow to very fast rates. The knob is scaled in this respect, giving finer control in the middle ranges. The overall rate range is 0.004 Hz to approximately 60 Hz. Centre position is around 5.3 Hz, which is ideal for pitch vibrato.
 - In **Osc** mode, the LFO operates at audio rate, becoming an additional keytracking oscillator. The values generated by the **Rate** control are linked to incoming MIDI notes, turning **Rate** into a control for transposition, ranging from zero when turned fully right, down to -96 semitones lower than the note pitch.
2. **Latch Rate:** When activated, changes to the **Rate** (via direct control or modulation) are latched until the next note is received.
3. **Amp Jitter:** Adjusts the amount of random modulation applied to the amplitude of the signal. Turned fully left, the basic waveform of the LFO is unaltered. Turning the knob right increases the amount of unpredictable values. When turned fully right, a completely random value is produced with each cycle.
4. **Freq Jitter:** Adjusts the amount of random modulation applied to the frequency of the signal. Turned fully left, the basic waveform of the LFO is unaltered. Turning the knob right increases the random frequency fluctuation. This can produce results similar to white noise, if **Amp Jitter** is set to a low value. **Freq Jitter** is only available in **Free** and **Osc** modes.

5. **Threshold:** Provides further treatment for the amplitude, and only has an effect if the **Amp Jitter** is turned up. Random values below a set **Threshold** are forced to zero, which can be used to drastically thin out the noise.
6. **Seed:** Adjusts the seed that feeds the random sequence introduced by **Amp Jitter** and **Freq Jitter**. This control is only available in the play modes **Loop RST**, **Loop GTE**, and **Loop REL**. Adjusting **Seed** produces a new random sequence, starting with the next reset event. You can use this to explore different randomly acquired waveforms and repeat them with every new note.
7. **Shape:** Adjusts the shape and smoothness of the ties between values. Technically speaking, it's applying a linear interpolation to the values. When turned fully left, a smooth interpolation is produced and when turned right, hard steps are created.
8. **Audio Noises:** When activated, the LFO operates in audio rate. This turns the LFO into a Noise generator, which when assigned to a modulation source in the Routing page, can be used in the audio signal path.
9. **LFO Level:** Amplifies the output of the LFO. Turning the knob right increases the amplification level.
10. **Polarity:** Selects from two Polarity settings (Bi, Uni) that determine how the envelope in the Amp section behaves. When **Bi** (Bipolar) is selected, the output range of the LFO is -100% to +100%. The waveform always starts at 0%, independent of which shape is selected. **Uni** (UniPolar) offers a range of 0 to 100%. The waveform will always start at 50%, independent of the selected shape.
11. **Delay:** Applies a delay to the onset of the LFO. When turned fully left, no delay time is applied and the LFO starts immediately. Turning the knob right increases the delay time.
12. **Fall/Rise:** Adjusts the way the LFO fades in or out. At center position the LFO has infinite falling time, working as though it is always on. Turning the knob right produces a short rising ramp that becomes longer as it is turned fully right. Turning the knob left creates a very small decay fall time, which extends to a very long falling time as the control is turned fully left. The display, located below the **Fall/Rise** knob, provides a visual representation of the shape of the fades.
13. **Mono:** When deactivated, the LFO is polyphonic. Each incoming note receives its own LFO. When activated, the LFO is monophonic and all incoming notes receive the same LFO, regardless of pitch.
14. **Midi:** Switches between Midi and Remote mode for resetting and latching the LFOs. When **Midi** is selected the LFO resets and latches based on incoming MIDI note events. If **Remote** is selected the LFO resets and latches when you change key switches in the Remote Octave.

15. Play mode: Selects from six settings (Loop, Loop RST, Loop GTE, Loop REL, 1shot, 1shot REL), that determine the general behavior of the LFO.

- **Loop** is the most classic setting, with the LFO running in an infinite loop, regardless of whether notes are being played or not. When turning **Amp Jitter** and **Freq Jitter** to the right, the waveform will randomly change over time.
- **Loop RST** (Loop Restart) also runs in an infinite loop, but will immediately jump to a given phase if a MIDI trigger is received from Zone or Remote. When turning **Amp Jitter** and **Freq Jitter** to the right, the waveform will change randomly over time, but start the same random sequence again upon receiving a MIDI trigger.
- **Loop GTE** (Loop Gate) follows the same behavior as Loop Restart, but cuts the LFO as soon as the note is released. When turning **Amp Jitter** and **Freq Jitter** to the right, the waveform will change randomly over time, but start the same random sequence again when the note is released.
- **Loop REL** (Loop Release) deactivates the LFO as soon as note is received. When the note is released, the LFO resets and the modulation is in effect. In this mode, it is important to set a long release time on the Amp envelope, or the effect will not be heard. When turning **Amp Jitter** and **Freq Jitter** to the right, the waveform will change randomly over time, but start the same random sequence again when the note is released.
- When **1shot** (One Shot) is selected, only one cycle of the LFO will be played. Note on will always restart the LFO and go to zero after the cycle, regardless of the LFO value or polarity setting. This ensures predictable results, regardless of the LFO waveform.
- **1shot REL** (One Shot Release) follows the same principles as **1shot** mode, but creates a cycle when the note is released. In this mode it is also important to set a long **Release** time on the Amp envelope, or the effect will not be heard.

To get started, try applying the Random LFO to the **Pitch** of an oscillator, or the **Wavetable Position**. Turn the **Shape** control toward the square shape to create rhythmic variations in pitch and timbre. Experiment with all the settings to hear the range of noises and random voltages you can create.

20. Trackers

The four Trackers are modulation sources that provide deep functionality for advanced keyboard tracking. They map incoming MIDI control data like pitch and velocity to modulation that you can apply to any parameter. This enables you to exactly define how your sound responds to the MIDI input.

i This feature is not available in Massive X Player.

The Tracker's Tracking view allows you to view and create curves and offset values that represent the relationship between the MIDI input and the modulation produced by the Tracker. Each Tracker can be used with one of five available sources: **Note Pitch**, **Velocity On**, **Velocity Off**, **Gate**, and **Inverse Gate**.

As an example, you can use **Note Pitch** to define the response of your sound to the pitch values of incoming MIDI notes. When setting the Tracker's curve to a linear, rising ramp, it can be applied to parameters for standard keyboard tracking, meaning low notes produce low parameter values, and high notes produce high parameter values. In this case, the values produced by each MIDI note increase linearly across the keyboard, from left to right. By changing the Tracker's curve from a linear, rising ramp to other shapes or even adding irregular offsets to it, you can break up this relationship. For instance, inverting the curve to a falling ramp would result in high parameter values when playing low notes and vice versa, or adding extreme offsets to specific notes would produce high parameter values only when playing the corresponding keys.

You can access and assign the Trackers in the Editor via the Navigation Bar using the tabs labeled **T1–T4**. For information about assigning the Trackers to parameters, refer to [Assigning modulation](#).

Learn how to use the Tracker in the following tutorials:

- [Using the Tracker to apply filter tracking to a sound](#): In this tutorial, you learn how to use the Tracker's Curve mode for advanced filter tracking.
- [Using the Tracker to create delay time variations in a sound](#): In this tutorial, you learn how to use the Tracker's Offset mode for recalling defined parameter values.

Trackers overview

This section provides an overview of the Tracker's features, including the Tracking view, the Source options, and the Edit modes.

1. **Source:** Selects the type of MIDI control data processed with the Tracker. The following sources are available:
 - **Note Pitch** is the MIDI note value. This option retains the pitch value until another note is played. Use this source if you want to track the pitch of the notes.
 - **Velocity On** is standard, note-on velocity. This option retains the velocity value until another note is played. Use this source if you want to track the velocity of the notes.
 - **Velocity Off** is note-off velocity. This option retains the velocity value until another note is released. Use this source if you want to track the note-off velocity of the notes.
 - **Gate** is standard, note-on velocity. This option resets the velocity value to 0 when a note is released. Use this source if you want to track the velocity of the notes you are playing, but only for as long as a note is held.
 - **Inverse Gate** is note-off velocity. This option resets the velocity value to 0 when another note is played. Use this source if you want to track the note-off velocity of the notes you are playing, but only for as long as no other note is played.

This is useful for controlling envelope parameters when a note is released without affecting the notes that follow.

2. **Level:** Sets the output level of modulation produced by the Tracker. At the left position, the output is at zero, at the right position, it's at 100%.
3. **Vertical grid:** Sets the vertical resolution of values in the Tracking view. By default, the number of available values is set to 24 (bipolar -24 to +24, unipolar 0 - +24).
4. **Snap to Grid:** Ensures the grid value is adhered to even when making fine adjustments by holding the right-mouse button and dragging.
5. **Select zone:** Click and drag in this area to select multiple breakpoints. The segments between them can be edited using the Segment Edit zone.
6. **Tracking view:** Here you can draw curves and offsets that define the Tracker's modulation output using the different edit modes. The content of the other Trackers is shown as greyed out curves or offsets in the background (depending on which type of content is active in the Tracker being edited).
7. **Segment Edit zone :** Use this area to edit single or multiple segments between breakpoints. Clicking and dragging moves the segments to a new position in the Tracking view. Right-clicking and dragging allows you to make fine-adjustments without snapping to the grid. Double-clicking deletes segments.
8. **Zoom bar:** Zooms and navigates in the Tracking view. Clicking and dragging the handles zooms in and out. Clicking and dragging the bar scrolls the contents. Double-clicking the bar zooms out completely.
9. **Edit mode:** Determines whether the Tracker's modulation output is defined by a curve, offsets, or a combination of the two in the tracking view. For more information, refer to [Tracking view and Edit modes](#).
10. **Range switch:** Sets the range of the Performer to bipolar or unipolar.
11. **Initialize:** Clears all curves and offsets, and resets the grid to bipolar or unipolar.

Tracking view and Edit modes

The Tracking view is used to establish the relationship between the MIDI input on the horizontal axis and the Tracker's modulation output on the vertical axis. It can contain a curve, offsets, or a combination of the two. This determines not only how you interact with the Tracker, but also its modulation output.

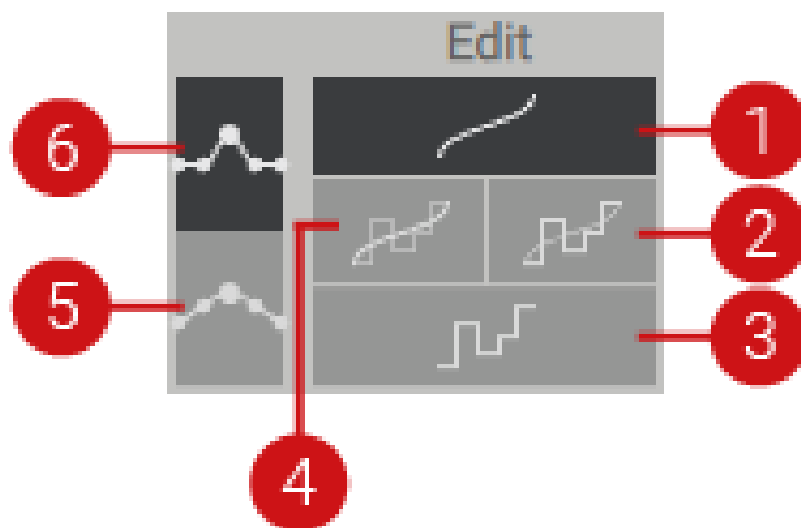

- The curve establishes the relationship between the MIDI input and the modulation output across the whole range. This is useful for generating modulation that responds to the MIDI input in a coherent way, adjacent MIDI input values will produce progressively changing modulation values. The shape of the curve can be set using any number of breakpoints, creating separate segments between them:

- The offsets establish the relationship between specific values of the MIDI input and the modulation output. This is useful for generating modulation that responds to the MIDI input in very specific, or unexpected ways. Each MIDI input value can produce any modulation value, hence abrupt changes in modulation are possible from one MIDI input value to the next. The offsets can be painted in for each value individually:

You can switch between curve and offsets using the different Edit modes:

1. **Curve mode:** Only the curve is active and can be edited. The following mouse interactions are available:
 - Clicking on the Tracking view creates a new breakpoint.
 - Clicking and dragging an existing breakpoint moves it to a new position.
 - Right-clicking and dragging allow you to make fine-adjustments in one direction without snapping to the grid.
2. **Combined Offset mode:** Both the curve and the offsets are active, however only the offsets can be edited. The following mouse interactions are available:
 - Clicking and dragging adjusts the offset for multiple values.
 - Right-clicking and dragging sets multiple values to 0.
 - Clicking, holding, and then dragging up and down adjusts the offset for a single value.
 - Right-clicking, holding, and then dragging up and down allows for fine-adjustments for a single value without snapping to the grid.
3. **Offset mode:** Only the offsets are active and can be edited. The following mouse interactions are available:
 - Clicking and dragging adjusts the offset for multiple values.
 - Right-clicking and dragging sets multiple values to 0.
 - Clicking, holding, and then dragging up and down adjusts the offset for a single value.
 - Right-clicking, holding, and then dragging up and down allows for fine-adjustments for a single value without snapping to the grid.
4. **Combined Curve mode:** Both the curve and the offsets are active, however only the curve can be edited. The following mouse interactions are available:
 - Clicking on the Tracking view creates a new breakpoint.
 - Clicking and dragging an existing breakpoint moves it to a new position.
 - Right-clicking and dragging allow you to make fine-adjustments in one direction without snapping to the grid.
5. **Absolute breakpoint editing:** Sets the behavior when editing breakpoints to absolute. Moving a breakpoint only affects the breakpoint and its corresponding segments. This option is only available in Curve mode and in Combined Curve mode.
6. **Relative breakpoint editing:** Sets the behavior when editing breakpoints to relative. Moving a breakpoint also affects the other breakpoints by shifting their position relative to a virtual rubber band. This option is only available in Curve mode and in Combined Curve mode.

Using the Tracker to apply filter tracking to a sound

Filter tracking is a common feature found in synthesizer filters that forces the cutoff frequency to follow the pitch of incoming MIDI notes. When filter tracking is applied, low notes result in lower cutoff values, producing a darker sound. High notes result in higher cutoff values, producing a brighter sound. All resonant filters in Massive X offer filter basic tracking.

However, by using a Tracker to apply filter tracking to a sound, you can fully control the response to incoming notes. You can use this to intensify the effect or create chaotic behavior. It is also possible to invert the response. In this case, low notes produce a brighter sound, and high notes produce a darker sound.

The following tutorial shows you how to apply filter tracking to a sound and change the response of the tracking:

1. Open Massive X and keep the preset **Init - Massive X** selected.

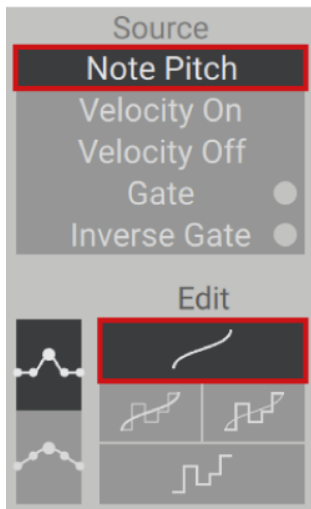

2. Set both the **Freq** and **Res** controls on the **Asimov** filter to noon.

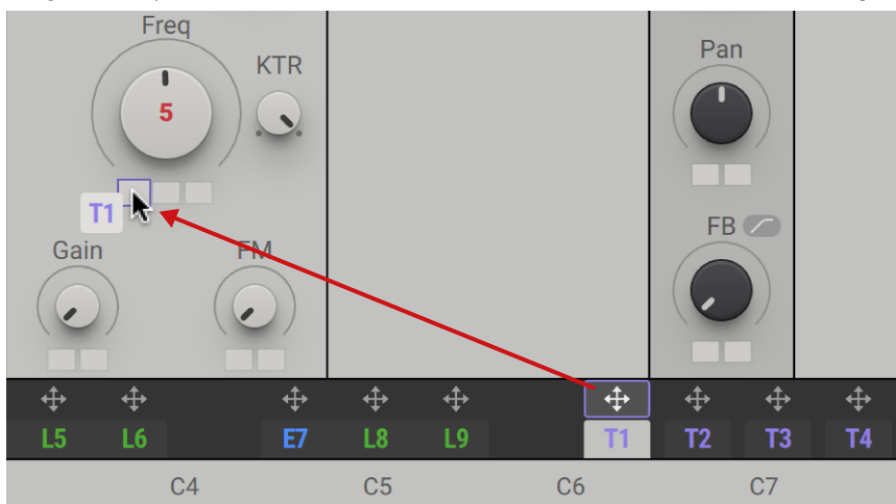

3. Select the Tracker **T1** in the navigation bar to show it in the editor.

- For this workflow, set the Tracker to **Note Pitch** and Curve mode. The preset **Init - Massive X** already includes the correct settings.

- Drag and drop the arrow icon for **T1** to the first modulation slot of the **Freq** control.

- Click and drag the first modulation slot of the **Freq** control up to set the maximum modulation amount for the Tracker.

7. Play some notes on your keyboard or a sequence in your host software. You can see the active note being highlighted by a vertical bar in the Tracker's Tracking view.

The curve in the Tracking view represents the values of the Tracker's modulation output (y-axis) for each MIDI note (x-axis).

8. Click on the curve in the Tracking view to create a new breakpoint.

9. Click and drag the breakpoint in any direction to adjust the curve and therefore the Tracker's response to incoming notes.

- 10 Repeat steps **7** and **8** to add a breakpoint in another position. By changing the position of the breakpoints, you can create a more extreme response to incoming notes. For example, by setting the breakpoints as shown below, the cutoff frequency rises strongly between notes **C1** and **C4**, but stays at the respective value outside of this range.

- The cutoff frequency follows the pitch of incoming MIDI notes relative to the curve in the Tracking view. In the example above, notes lower than C1 produce a dark sound with the cutoff frequency at a minimum. Between C1 and C4, the sound becomes brighter with every note. Notes higher than C4 produce a bright sound with the cutoff frequency at the maximum.

- 11 To invert the response of the tracking, drag all breakpoints including the ones at the two ends of the curve fully up or down, respectively. Following the example above, the inverted curve is as follows:

- The cutoff frequency follows the pitch of incoming MIDI notes in an inverted fashion: low notes produce a brighter sound, and high notes produce a darker sound.

Using the Tracker to create delay time variations in a sound

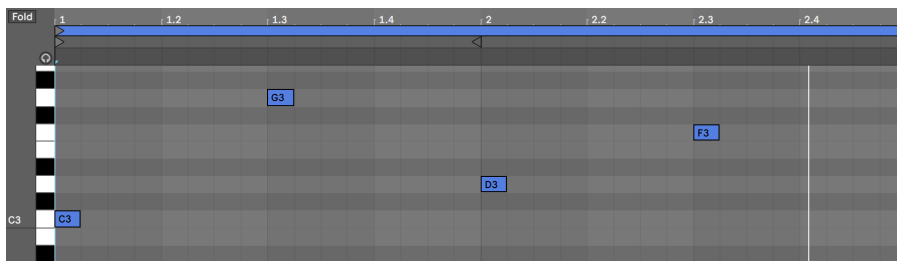

The Tracker's Offset mode can be used to make a sound respond to incoming MIDI notes in a very specific way. When combined with the Source **Note Pitch**, the modulation produced by the Tracker is defined independently for each note, by drawing in single values in the Tracking view. This is useful for fine-tuning a sound's behavior at specific pitches, or for creating anything from subtle to drastic sound variations across the keyboard.

The following tutorial shows you how to use Offset mode to recall defined delay time values when playing specific notes:

1. Open Massive X and select the preset **Advanced Optics**.

2. You can play the preset from your keyboard, however for this tutorial we recommend to program and play back a sequence of short notes with long pauses.

3. Turn the **FX** macro fully clockwise to make the echo effect in this preset more pronounced.

4. Show the Stereo Delay effect by clicking on the **Z** Stereo Effect slot.

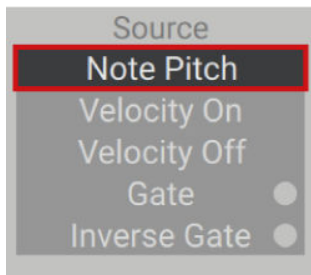

5. Adjust the individual delay times next to the delay time fader to create a variety of rhythmic echo effects depending on the position of the control.

6. Select the Tracker **T1** in the navigation bar to show it in the editor.

7. For this workflow, set the Tracker to **Note Pitch** mode. The preset **Advanced Optics** already includes the correct setting.

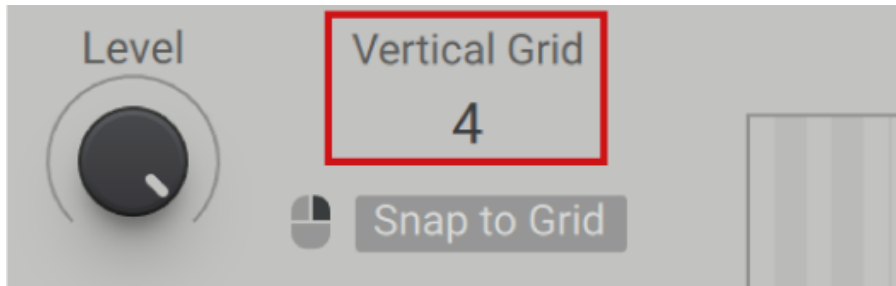

8. Enable Offset mode in the left area of the Tracker.

9. Set the resolution of the **Vertical Grid** to **4** in the left area of the Tracker.

i By setting the resolution to **4**, the **Vertical Grid** corresponds to the number of available values for the delay time control. This makes it easy to adjust the offset amounts in a meaningful way.

- 10 Drag and drop the arrow icon for **T1** to the first modulation slot of the delay time control.

- 11 Click and drag the first modulation slot of the delay time control up to set the maximum modulation amount for the Tracker.

- 12 Play back the previously programmed sequence in your host software. You can see the active note being highlighted by a vertical bar in the Tracker's Tracking view.

The offsets in the Tracking view represent the values of the Tracker's modulation output (y-axis) for each MIDI note (x-axis).

- 13 Click and drag the offset amount for one of the notes in the sequence to change the Tracker's response to this note.

- 14 Repeat step 12 for the other notes in the sequence. By changing the offset amounts, you can
- define the delay time for each note independently. For example, by setting the offset amounts as shown below, **C3** recalls a delay time of **1/8** (first value of the control), **D3** recalls **1/16** (second value of the control), **F3** recalls **4/16** (fourth value of the control), and **G3** recalls **3/16** (third value of the control).

- The delay time responds to specific MIDI notes relative to the respective offset amount. In the example above, the notes C3, D3, F3, and G3 each recall different delay time values for a variety of rhythmic echo effects.

21. Voice Randomization

Voice Randomization is a modulation source that allows you to add pseudo-random variation to your sound. It generates a fixed modulation value per voice that can be applied to parameters, giving them a different value depending on which voice is played. For example, this can be used to create subtle differences in tuning between voices like on an analog synth or to create dramatic effects by completely changing the sound per voice.

You can assign Voice Randomization via the Navigation Bar using the arrow icon labeled **VR**:

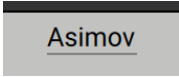

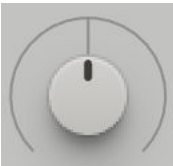

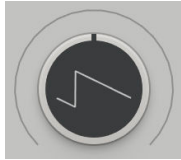

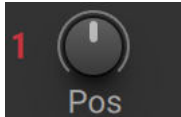

For information about assigning Voice Randomization to parameters, refer to [Assigning modulation](#).

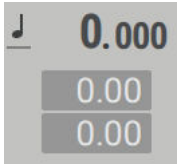

i This feature is not available in Massive X Player.

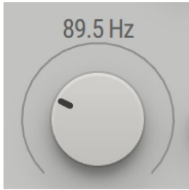

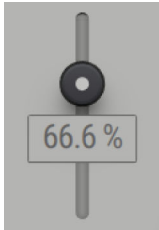

22. Control elements

Massive X's user interface features a number of different controls. The following overview explains how to interact with them using a mouse.

Name	Image	Description	Key commands
Dropdown menu		Used to select from a list of options relating to the respective section or function.	<ul style="list-style-type: none"> Click opens or closes the dropdown menu. Click on any of the available entries selects the corresponding option and closes the dropdown menu.
Dropdown menu (with display)		Used to select from a list of options relating to the respective section or function. The selected entry is visualized in the display.	<ul style="list-style-type: none"> Click on either the name or the display opens or closes the dropdown menu. Click on any of the available entries selects the corresponding option and closes the dropdown menu.
Dropdown menu (extended)		Used to select from a list of options relating to the respective section or function.	<ul style="list-style-type: none"> Click opens or closes the dropdown menu. Click on any of the available entries selects the corresponding option and closes the dropdown menu. Placing the cursor over the dropdown menu shows arrow icons that can be used to select the previous or next entry from the list, respectively.
Unipolar knob (with modulation)		Used to adjust parameters in the range of 0% to 100% from left to right.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Bipolar knob (with modulation)		Used to adjust parameters in the range of -100% to +100% from left to right. The center position is 0%.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.

Name	Image	Description	Key commands
Wavetable knob		Used to adjust the wavetable position of the corresponding Wavetable oscillator. The display at the center of the control visualizes the resulting waveform.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Unipolar knob		Used to adjust parameters in the range of 0%-100% from left to right.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Bipolar knob		Used to adjust parameters in the range of -100% to +100% from left to right. The center position is 0%.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Macro knob		Used to adjust parameters assigned to the Macro. Refer to Macros .	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Macro icon		Used to assign a Macro to parameters. Refer to Macros .	<ul style="list-style-type: none"> Drag + drop onto a control or a modulation slot assigns the Macro to the corresponding parameter.
Controller icon		Used to assign the respective midi controller to parameters. Refer to Macros .	<ul style="list-style-type: none"> Drag + drop onto a control or a modulation slot assigns the MIDI controller to the corresponding parameter.
Page tab		Used to show the respective page in the Editor.	<ul style="list-style-type: none"> Click shows the page in the Editor.
Modulation source tab		Used to show the respective modulation source in the Editor.	<ul style="list-style-type: none"> Click shows the modulation source in the Editor.
Modulation icon		Used to assign a modulation source to parameters. Refer to Assigning modulation .	<ul style="list-style-type: none"> Drag + drop onto a control or a modulation slot assigns the modulation source to the corresponding parameter.

Name	Image	Description	Key commands
Pitch control		Used to control the pitch and pitch modulation amounts of components that track MIDI pitch.	<ul style="list-style-type: none"> Click + drag on the integer number changes the pitch in semitones. Click + drag on the decimal places changes the pitch in cent.
Numeric control		Used to adjust parameters in a specific range of values.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Rotary selector		Used to select from a predefined set of different states or values.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value. Click on icon in circle sets the corresponding value.
Slider		Used to adjust parameters in the range of 0% to 100% from bottom to top.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value.
Quantized slider		Used to select from a user-defined set of different states or values.	<ul style="list-style-type: none"> Click + drag up/down changes the control's value. Double click sets the control to its default value. Click + drag on any of the adjacent numbers changes the corresponding value.
Function button		Used to switch functions on or off.	<ul style="list-style-type: none"> Click toggles between the control's active and inactive state.
Module button		Used to switch modules on or off.	<ul style="list-style-type: none"> Click toggles the module's bypass function.
Auxiliary button		Used to switch auxiliary functions related to adjacent controls on or off.	<ul style="list-style-type: none"> Click toggles between the control's active and inactive state.

Name	Image	Description	Key commands
Mode selector		Used to select one of several modes.	<ul style="list-style-type: none"> Click on one of the buttons in the mode selector selects the corresponding mode.
Routing module		Used to make connections between modules on the Routing page.	<ul style="list-style-type: none"> Click + drag moves the module to a new position. Right click toggles the modules bypass function. Double click removes all connections from the module. Click + drag from an output node to an input node creates a connection. Alternatively, successive clicks on the two nodes can be used.
Parameter readouts for knobs		Used to display the exact value of a knob control.	<ul style="list-style-type: none"> Hover over a knob to display the parameter value above the control. Click + drag the control to adjust the parameter whilst displaying the value.
